FOREWORD

The concept of development and the role of planning in India has been clearly perceived from the very beginning. The First Five Year Plan, which marked the beginning of a new era of development under the stewardship of our great leader Pandit Jawaharlal Nehru, said :

"The central objective of planning in India ... is to initiate a process of development which will raise living standards and open out to the people new opportunities for a richer and more varied life... Economic planning has to be viewed as an integral part of a wider process aiming not merely at the development of resources in a narrow technical sense but at the development of human faculties and the building up of an institutional framework adequate to the needs and aspirations of the people".

This has been the frame of reference all these years. The Eighth Plan reiterated the human development goals. Prime Minister Shri P.V. Narasimha Rao, in his foreword to the Eighth Plan, wrote :

"...Human Development, in all its many facets, is the ultimate goal of the Eighth Plan. It is towards fulfilling this goal that the Eighth Plan accords priority to the generation of adequate employment opportunities to achieve near-full employment by the turn of the century, building up of people's institutions, control of population growth, universalisation of elementary education, eradication of illiteracy, provision of safe drinking water and primary health facilities to all, growth and diversification of agriculture to achieve self-sufficiency in foodgrains and generate surpluses for exports..."

Needless to state that economic growth and social development are both important for achieving the ultimate goal of human development.

Matching of resources and instrumentalities with the goals of development requires substantial amount of technical work. Potential of resources, nature and quantities of investment in different sectors, balance of payments constraints, energy and infrastructure requirements, efficiency of use of resources or incremental capital-output ratio, etc., are all to be assessed in constantly changing situation. These have all to be assessed in a certain framework where relationship of one variable with another is clearly defined on the basis of real behaviour of the economy. Assessment of those relationships is necessarily an on-going process. The framework which defines these processes is called a "model" in the jargon of economists. These models express the relationships in mathematical terms. Historically, planning models have played two roles. One was that of defining a strategy of development, i.e., answering questions of priority between industry and agriculture, between heavy industry and light industry, between consumer goods and investment goods, etc. Mahalanobis model was an important landmark in this category of models. The other role of planning models has been that of assessing parameters and arriving at targets which are consistent with resources on one hand, and mutually consistent on the other. It is this second category of models which have to be constantly estimated and updated.

The Eighth Plan was finalised in a relatively short period of time. All the necessary technical work had been done for this purpose. However documentation of the technical work has taken sometime. The staff of the Perspective Planning Division under the leadership of Professor S.R. Hashim has done a painstaking job in this respect. Dr. Arjun Sengupta, Member-Secretary of Planning Commission has provided the overall guidance. The technical work of the Eighth Plan also benefitted from the guidance from Dr. C. Rangarajan, Member, Planning Commission during the period when the Eighth Plan was being finalised.

Our perception about the effective working of the economic system has been changing in the light of our own experiences. We took a major step in initiating economic reforms since 1991. Under the reformed system, market and decentralised decision making will play larger role in economic system, thus releasing new economic energy for fast growth and more effective development. Planning instruments and planning models will also have to adopt to the new situation. Dr Arjun Sengupta, Member- Secretary, Planning Commission has taken new initiatives in networking with some of the most prominent national and international modelling groups and academicians with Planning Commission playing a nodal role in developing suitable modelling frames which answer more adequately to the needs of the changed economic scenario I very much hope that the results of these efforts will be available for use in the formulation of the Ninth Plan. The present Technical Note provides a base line on which further structures can be developed.

PREFACE

Indian planning process is extremely complex. it involves outlining the strategies for development and the supporting policy environment, working out the macro-parameters for the growth and its sectoral pattern, allocation of resources between centre and states and for different sectoral activities, detailed allocation of budgetary support and consideration of specific projects/programmes and schemes in the public sector. Formalised modelling is used for working out the macro-parameters for growth and its sectoral pattern and allocation of resources for different sectoral activities. Since the Fifth Plan, the numerical exercises and the technical work at the back of the formulation of the plan are being presented separately in the form of a technical note. The technical note outlines the methodology of plan formulation in detail by capturing the diverse inter-relationships of forces and factors that lie behind the national plan and describe in detail the various assumptions, techniques and analysis that form the basis of the plan. From this point of view, the technical notes have been found very useful. The Eighth Plan Technical Note is the fourth in this series. This note describes in detail the technical work that went behind formulation of the Eighth Plan and contains eight chapters. Chapter-1 presents the mathematical framework of the multi-sectoral input-output model which is used to derive mutually consistent sectoral output targets and corresponding sectoral investment demands. A set of sub-models have been used to assess the impact of those variables which are not adequately captured through the input-output frame. Chapter-2 describes demography and employment. Chapter-3 describes the financial resources sub-model. A detailed description of the determination of the agricultural output targets are provided in Chapter-4. Chapter-5 gives industry sub-model. The methodology adopted for projections of export and import are covered under trade sub-model in Chapter-6. Chapter-7 outlines the method of estimation of sectoral private consumption in consumption sub-model.

Launching of the Eighth Five Year Plan also coincided with major initiatives in economic reforms and liberalisation. In the changed economic environment, market will play a larger role, private sector would be expanding and the public sector would become increasingly more autonomous and subject to market forces. The international trade will start having larger impact on the domestic economy. The Government will be in social sectors and in creating a suitable environment for growth and development including infrastructure. This will require some re-orientation in the planning process. Some thoughts along these lines have been spelt out in Chapter-8.

Needless to say that technical work relating to the preparation of the plan demands cooperation, collaboration and active participation of all the Divisions in Planning Commission. Such help was available in full measure.

Work on the Eighth Plan had started much before the Eighth Plan began. Guidance of Dr. C. Rangarajan, the then Member, Planning Commission was very valuable during the period of the finalisation of Eighth Plan and the related technical work. However, the write-up on technical note was somewhat delayed. It was the keen interest shown, encouragement given and guidance provided by Dr. Arjun K. Sengupta, Member-Secretary, Planning Commission which enabled us to bring out the note in its final form.

A team of officers of the Perspective Planning Division undertook the final drafting of the note. The team was led by Shri K. L. Datta and included Mrs. Savita Sharma, Shri Mohan Chutani, Shri Rajeev Malhotra, Shri R K. Chandolia, Shri Subroto Dhar, Shri S.V. Ramana Murthy and Shri A'ok Kumar.
The sub-model on trade has been prepared by Shri Prabhu Dayal with the assistance of Shri M.R. Verma. Shri J. Satyanarayana was intensively involved in the modelling work at the time of the preparation of the Plan. Shri R K Pruthi, Technical

INTRODUCTION

A Five Year Plan is conceived in terms of a set of social and economic goals. Feasibility of achieving these goals depends on availability of resources and other enabling conditions. Checking the feasibility of goals against enabling conditions itself requires elaborate technical work. How much of financial resources can be made available in the future, how the saving behaviour would change or how it could be modified, what would be the balance of payments constraints or the resource use efficiency, etc., are some of the concrete questions of macro-economic nature which have to be answered. Yet another set of questions pertain to the instrumentality of achieving the goals. These instrumentalities could relate to physical conditions, like availability of necessary infrastructure and essential inputs, energy, technology, etc. Instrumentalities could also relate to policies and institutions and mobilisation of resources.

The relationship between the goals, macro-economic parameters and physical conditions are amenable to modelling in terms of a set of defined mathematical relationships. Technical work of the plan pertains to determining the exact nature of these relationships as well as preparing the suitable data-base for the plan

This technical note describes the mathematical models and quantitative work that lies at the back of the formulation of the Eighth Five Year Plan The use of formal mathematical models in capturing the economic realities and spelling out the development philosophy started from the early days of planning The path-breaking exercise of P.C. Mahalanobis culminated in the formulation of a mathematical model which guided India's planning strategies right from the early days, particularly since the formulation of the Second Plan. This model came to be known as Mahalanobis model

Leontief Input-Output table which details out the precise relationship between the output of an industry and the inputs drawn from other industries to produce that output, became a very powerful instrument in determining economic interrelationship between different sectors of production With the construction of the Leontief input-output tables for India during the early sixties, input-output tables came to be used in the projection of long term economic growth scenario and also for working out sectoral output and investment consistency of the Fourth Plan. For the Fifth Plan, Prof. Sukhomoy Chakravarty evolved a model integrating the models of Harrod-Domar type and the Leontief input-output system in a demand-supply frame relating growth with investment. Thus we had a plan model which integrated macro- economic parameters with the consistency requirements at a more disaggregated level of intersectoral relationships. The model has undergone some variations overtime. More variables have been endogenised in successive plans The Eighth Plan model belongs to this family of models where investment, consumption and imports - the three major variables determining the growth rate and the level of living are endogenously determined in the model.

The model system used in the Eighth Plan exercise comprises of a core model and a set of inter-linked sub-models The core model consists of macro-economic model, input-output model and investment model. The sub-models are for Agriculture, Financial Resources, Consumption, Industry and Trade. A simple description of the working of the model systems is given in what follows.

To start with we make an estimate of investible resources which the economy could make available over the Plan-period. At the macro level those re-sources are called savings. Savings depend both on income levels and on habits (i.e , observed behaviour). Income levels, or the way the income would grow over the plan period is not certain at this stage. So we work with a few alternatives. Savings behaviour is assessed from past observations of how different saving agents have

behaved over time or how they have responded to various instruments (i e policies) adopted to modify that behaviour in the past Main saving agents are households Government public enterprise sector and private corporate sector An estimate of resources available from abroad is also made and when added to the savings it gives estimate of investible resources available over the Plan period

It so happens that agents who generate savings need not make investments in equal amounts A large part of savings of households gets invested by Public sector or Private Corporate sectors Savings change hands through financial institutions Hence an estimate of such flows among the saving and investing agents has to be made In doing this investment capabilities and investment needs of various investing agents are taken into account Since the model has not yet been fully worked out these estimates are tentative and serve as a starting point These may get revised in the light of the final result of the model and then the full model has to be worked out again beginning from this point Thus though the planning model is largely sequential it does become iterative in actual working because some variables have to be fed from outside the model (i e they are not fully endogenised)

Then there is the estimate of a relationship between investment and output at the level of the economy This is known as capital output ratio Where this ratio pertains to the investment made during the plan period and additional output/income to be generated during the period it is known as Incremental Capital Output Ratio (ICOR) This is estimated for the economy on the basis of the past observations and future prospects

Given the investible resources and the ICOR one has an idea of the rate of growth which could be targetted/achieved Since this point marks the beginning one has to start with a few alternative estimates of resources ICOR and achievable rates of growth

Savings Investments Gross Domestic Product and its rates of growth are all part of macro model Also in this macro model are included the other related variables such as exports imports balance of payments and fiscal variables i e revenue expenditure savings and borrowing of the Government

The next stage in the exercise is to work out at more detailed level the final demands in keeping with the indicated levels of output in the macro model The final demands consist of private consumption public consumption exports imports and capital formation (including change in stocks) Each of these has to be worked out at such levels of disaggregation (o by as many industries and sectors) as is the level of disaggregation of the Input Output Table

The Input Output Table used in the Eighth Plan had 60 sectors and its reference year was 1991 92 i e the base year of the Plan This Table was prepared by updating and re calibrating a basic input output table prepared by the CSO for the year 1983 84 The input output table yields an input coefficients matrix in which inputs used in an industry are expressed as quantities per unit of output of that industry The input coefficient matrix for the terminal year of the plan is projected from the coefficient matrix of the base year after incorporating the anticipated changes in product and technology mix on the basis of information available for various sectors or industries in the economy

The core model brings forth the interaction between a set of final demand elements (vectors or columns) and the input output matrix which represents the inter industry relationships as well as the state of technology For each of the elements of final demands there is a separate sub model

The consumption sub-model estimates private consumption demand for different goods and services, taking into account the growth pattern of the economy as postulated in the Plan, the projected growth in population and its rural-urban composition and the inequality in consumption distribution. Private consumption is divided into four segments : rural and urban, and each into poor and non-poor groups of population. The model incorporates the parameters of consumer behaviour for each of these separate segments of population. A detailed exercise is done for assessment of the poverty cut-off points and the pattern of distribution of consumption for poor and non-poor. The consumption model, in effect, quantifies the extent of improvement in levels of living as a result of increase in per capita consumption expenditure and reduction in the disparity of consumption expenditure between different income classes of the population. The changes in consumption expenditure during the plan period suggest a relatively higher growth in per capita terms in rural areas as compared to urban.

The investment necessary to generate the desired level of output at sectoral level is worked out in the investment sub- model. Investment requirements of different sectors are known as "investment by destinations" and the type of capital goods which form the investment are known as "investment by source" in the model. The relationship between outputs and investments are assessed through econometric techniques (or econometric models) Aggregate gross investment in a sector consists of new investment and replacement investment. New investments are geared to capacity creations. Sectoral investment is again divided into committed investment for on-going projects and investment for projects initiated during the plan period. Investment to output relations have a gestation lag as investments are spread over a number of years before a project or programme starts generating output.

The model treats public and private investments separately, as allocation of investment in public sector is a target while that in private sector is an indicative forecast. Finally, the model checks the consistency of output requirements in the post-plan period with long term objectives and matches it with the growth potentials of the Plan.

The final demand elements of imports and exports are projected with the help of the trade sub-model which estimates exports and imports in conjunction with balance of payments and current account deficit. The current account deficit, in turn, becomes the foreign component of investible resources of the economy.

Import requirements are broadly of two types. One is of those imports which are required in the production process. The other is of those imports which balance the gap between demand and production for consumption purposes. Production related imports are estimated through an import matrix which is a sub- matrix of the input-output table, and describes in detail the import input requirements of each industry.

The projected levels of imports in conjunction with the desirable level of current account deficit, which in turn has implications for foreign debt and debt servicing, determines the needed level of exports in aggregate. This aggregate level of exports is then disaggregated into commoditywise exports on the basis of commoditywise feasibility studies based on past trends and future prospects. These also have to take into account the policy changes and the World trade environment.

After the final demand components, disaggregated by industries/sectors (or "final demand vectors"), have been worked out, the consistent production levels can be worked out. These production levels would enable final demands to be met, while at the same time fully meeting the needs of industrial consumption (inputs). This exercise is accomplished through the core model, which has input-output matrix at its base. This exercise is undertaken for alternative sets of final demand, implying alternative sets of growth possibilities. The set in which the detailed exercise is

consistent with the set of macro-parameters worked out in the beginning is finally considered feasible.

At the detailed production level, two more checks are provided to check the feasibility of production for agriculture and to check the demand supply balance for important industrial outputs. This is done through two sub-models which are known as Agriculture sub-model and Industry sub-model respectively.

Agriculture sub-model essentially checks the feasibility of levels and growth of production of important commodities in agriculture. This is done specially for agriculture because the land and water constraints operating on the output of this sector do not get fully reflected in the input-output matrix.

Feasibility of agricultural output targets is determined in relation to type of land use, availability of irrigation and fertiliser application levels. The parameters relating to cropping intensity, area under irrigation and rainfed crops as well as area under high yielding and traditional variety of seeds by major crops at regional level are measured. The Plan objectives of growth and diversification of agriculture, self-sufficiency in food and generation of surpluses for exports are further assessed through the parameters estimated in the agriculture sub-model.

The Industry sub-model deals with outputs of selected industries or commodities and checks at the demand-supply balances as well as capacity-use constraints. Sectoral estimates of capacity and output, along with likely absorption of the commodity in major consuming sectors are worked out at a disaggregated level. The estimates of output are worked out in physical units, as the commodities are considered at more homogenous levels. The commodity-wise demand and supply within each input-output sector is obtained through material balance studies. Successive stages are . (i) identification of major consuming sectors and their sub-sectors, their current production and targets of production in the Plan, (ii) determination of input norms in the past on the basis of observed data and adopting these for future period in the light of relevant technical information, (iii) calculation of material requirements from the targets of production of user sector and the input norms, and (iv) estimation of addition to stocks and other uses.

Material balances are prepared for key products such as coal, electricity, petroleum products, steel, heavy machinery and petro-chemicals, sugar, cloth, jute, non-ferrous metals.

The starting point of the entire exercise, as discussed earlier, is the assesment of investible resources This exercise is further taken up in detail in the Financial Resources sub- model.

The financial resources sub-model estimates the availability of resources in order to finance the investment needs estimated in the input-output and investment model necessary to generate the desired growth rate. The sub-model assesses the level of domestic savings sectorally as well as in terms of its composition using econometric estimation procedure. These estimates are consistent with the macro aggregates of the plan. The estimate of resource in the Financial Resources sub-model is procedurally recursive to the input-output cum investment model due to the simultaneity between savings and income.

The aggregate savings function is estimated by regressing Gross Domestic Savings (GDS) on Gross Domestic Product (GDP) The elasticity of domestic savings with respect to GDP is estimated from appropriate savings function. The Eighth Plan postulates that both the marginal propensity and the average propensity to save during the plan period would be of the same order.

Household savings is estimated on the basis of it's functional relationship with household disposable income. The marginal rate of household saving and the elasticity of household savings are estimated with respect to household disposable income. The savings of the household sector in the form of physical assets are independently estimated by relating them to gross capital formation in terms of productive assets. The relationship between gross physical assets and gross disposable income of the household sector is assessed by regressing the former on household disposable income.

Savings in the public sector are estimated separately for Government sector and public enterprises in the framework of National Accounts. The savings of Government sector are assessed from a detailed analysis of various components of income such as direct and indirect taxes, non-tax revenues and public expenditure. The savings of public sector enterprises are assessed from the enterprise level analysis of their operational performance evaluated in terms of return to investment and retained profits. The savings of private corporate sector is assessed separately.

The scheme of financing pattern of public sector plan consists of budgetary support to the plan and internal and extra budgetary resources (IEBR) of public enterprises. This is backed up by inflow of foreign savings. The inter sectoral flow of funds in terms of flow of household savings to public sector is worked out from an analysis of the financing system embracing the structure of interest rates and other monetary and financial variables which govern the relative rates of return in public and private enterprises.

The Five-Year Plan has to be set within a perspective of long term growth and constraints, including the long-term demographic trends and constraints on basic resources, like land, water, energy and environment. The Eighth Plan has been formulated against the background of a perspective covering the period of 15 years from 1991-92 to 2006-07. The perspective of development visualises elimination of poverty and unemployment, a certain level of food consumption, reduction in disparity between urban and rural areas in respect of income and consumption and meeting the basic socio-economic needs and aspirations of the people. The factors which basically influence the scenario of the perspective plan are demographic trends and basic resource endowments. The structure of population growth and the associated growth and size of labour force characterize the demographic trends. Basic resource endowments are assessed in terms of land ,water, energy and other essential minerals and environment.

The output level of the terminal year of the Eighth Plan serves as the base for projections of growth in the future. The sectoral production levels in the perspective period are estimated from the input output model on the basis of exogenously estimated values of the macro variables, keeping the base level technology co-efficient matrix and other associated parameters generally unchanged. The feasible growth rate consistent with the long-run projection of sectoral demand was set at 5.6% per year for the plan period and 6.2% per year in the post-plan period. The pattern of long term growth in the perspective period is thus consistent with the investment policy framed in the plan, keeping in view the socio-economic requirements of the population. The growth rate in the post plan period estimated as 6.2 per cent per year was revised marginally upwards to 6.28 per cent per annum considering related improvements in efficiency in key areas and institutional reforms. The model results are based on an exogenously determined savings rate of 23.9 per cent and investment rate of 24.9% in the post-terminal period.

Since the model described above is basically a production and investment model, the social objectives of the plan get integrated into the model only through their additional consumption requirements or through their additional investment requirements both of which become part of the final demand in the system. Thus, when people cross the poverty line during the plan period their consumption requirements

change and increase and these have to be provided for when more of schools and hospitals have to be built these add to the investment requirements and in consequence requirements of producing more cement, bricks and medical equipments. However, the instrumentalities of bringing people above the poverty line have to be worked out outside the model. These are essentially social processes and necessitate social mobilisation, institution building and adopting a set of socio-economic policies. Model, as it is, yields a set of production and investment levels, and given the existing levels of techniques and the trends in technology, it will yield a given level of employment in the system. But if the need for employment is more, then policies and patterns of growth will have to be adopted which yield higher levels of employment To a very large extent such policies by way of pattern of growth are already inter-woven in the model, though they are not mathematically tractable. A particular emphasis on agriculture and related inputs, sufficiency of food production, etc., for example, are a part of the pattern of growth But most of the policies and details of programmes related to social objectives have to be worked out outside the model

Thus, the model is a crucial step in plan-formulation though it is not the entire plan.

CHAPTER - 1
THE MODEL STRUCTURE

The quantitative modelling and associated numerical scheme of calcu-
lation of the Fifth Plan which by all means was the handiwork of late Professor
Sukhamoy Chakravarty, changed the language and approach of Indian planning. The
scope of the change in the approach of planning in India since then has largely been
conditioned by what Prof. Chakravarty articulated nearly two decades ago in the form
of integration of the models of Harrod-Domar type and Leontief input-output system.
The models used in Indian planning since then have relied on extending this approach
in a demand-supply frame.

The model system used in the Eighth Plan exercise comprises of a core
model and a set of inter-linked sub models. The core model consists of:

(i) Macro economic model,

(ii) Input-output model, and

(iii) Investment model

A multi-sectoral input-output model is used to derive mutually consistent
sectoral output targets and corresponding sectoral investment demands. The model
frame is enveloped by a family of sub-models which play a crucial role in unfolding the
details of the intricacies of economic interdependence which are complementary to the
core model. Thus, the guiding spirit of the model is inter-industry consistency. No
attempt is made at approximating social optimality.

The requirements for consumption and investment, each separated into
public and private sectors, demand for export and import and of intermediate goods are
first assessed in tune with the various objectives set in the plan. These estimates of
demand, both sectoral as well as aggregate, are worked out in the core model. While
the consistency of output levels is assessed through the input-output model, their supply
feasibilities are checked mainly through the sub-models. The sub-models play a crucial
role in estimating the sectoral supply potentials. The sub models are estimated
separately and their integration with other sub models and the core model is achieved
by iterative processes.

I. Macro-Economic Model

The macro-economic model provides medium and long term projections
for (a) gross domestic product (GDP) at factor cost which is consistent with the desired
growth rate in the plan, and (b) total investment. These projections are based on a
number of structural relationships, most of which are in the form of income and
expenditure identities developed within the model. The forecast estimates of the macro
variables such as gross domestic product, public and private consumption, savings,
investment and net inflow from the rest of the world are worked out by balancing income
and expenditure for a series of alternative growth rates of income (or GDP) during the
plan period. The set of estimates which is found consistent with the aggregate savings
behaviour and domestic production possibilities is adopted.

Aggregate import in the terminal year of the plan is obtained from the
input-output model. Aggregate consumption and exports adopted in the model are
determined exogenously. Net revenue from indirect taxes is also treated as exogenous.
This coupled with the aggregate gross domestic product at factor cost produces the
gross domestic product at market prices. The estimate of investment in the macro model

1

is matched with the investment need assessed from the investment model. The model ensures aggregate macro economic balances amongst income and expenditure, comprising aggregate gross domestic product public and private consumption, savings, investment and net inflow from the rest of the world.

II. Input-Output Model

The core of the Plan model is the input-output model which has an input coefficient matrix based on a calibrated input-output table taking into account the economic flows of the base year of the Plan. In the input-output model where the entire economy is divided into 60 sectors supply and demand of the product of each sector is fully balanced. The intermediate demand of each sector is obtained through inter-relationships amongst different sectors using input-output coefficients representing the technology of production process. The final demand of the product of each sector is determined separately in respect of private consumption, public consumption, gross fixed investment change in stocks and export. The consumption demand is endogenous in the model on the assumption of likely changes in consumption distribution parameters separately for rural and urban areas. The import vector, i e, sectorwise imports is determined mainly as input requirements in the production system, through the input output model.

The scalar values of the macro variables relating to final demands estimated in the macro model are transformed into vectors in the input-output model. The final demand vectors consist of final private and public consumption external trade and investment. The final demand vector though exogenous to the input-output model, is none the less governed by the overall target rate of growth and also the observed internal economic relations expressed in terms of import coefficient matrix governing the trade vectors production functions governing the investment vector and consumption parameters expressed in terms of consumption expenditure elasticities governing the private consumption expenditure.

The scalar values of Government consumption gross fixed investment and changes in stocks are transformed into vectors in the input-output model. Private final consumption vector is worked out from the consumption model. The aggregate level of export in the macro model is largely a balancing item balancing the balance of payments account after imports are endogenously determined and current account deficit is exogenously targetted. The export vector is exogenously determined on the basis of past trends future potentials and promotional possibilities. Sectoral changes in stocks are obtained as fixed proportions of the increase in output levels of different sectors. These final demand vectors are added to arrive at aggregate final demand, which is used in conjunction with the input output matrices (Leontief inverse) to derive output value added and imports for each sector of the input-output model. The rates of indirect tax net of subsidies are then prorated to the base year so that the estimates of net indirect taxes generated in the macro model agree to that obtained from its sectoral estimates.

The structure of input output model used in the Eighth Plan exercises is described below.

a) Inter Industry Flow Matrix

The plan projections are based on 1991-92 as the base year. An input output table for 1991-92 has been constructed using the inter-industry transactions matrix for the year 1983 84 produced by the Central Statistical Organisation (CSO) Department of Statistics Ministry of Planning. The inter industry flows in the input output table of 1983 84, which is originally constructed for 115 sectors, has been aggregated into 60 sectors for use in the Eighth plan exercises. The inter-industry table of 1983-84 is updated to 1991-92 on the basis of input norms, commodity output, exports, imports investment, public and private consumption each at the prices prevailing in 1991-92. The price index used to update the input-output table has been

developed in two stages. First, the actual price rise between 1983-84 and 1989-90 has been assessed for each sector from the detailed data on wholesale price index as available from the Office of the Economic Adviser, Ministry of Industry, Government of India. Then, for the period 1989-90 to 1991-92, a forecast estimate of the price rise developed on the basis of past trend has been used to arrive at 1991-92 prices. (This way, the prices prevailing in 1991-92 is a forecast estimate based on the actuals until 1989-90). This updated input output table is balanced with the sectoral estimates of output and final demand of the base year of the plan.

b) Sectoral Output

The sectoral outputs in the base year are estimated on the basis of the commodity outputs of approximately 300 items in 1983-84 and 1991-92 in terms of their values and physical production levels. The sectoral outputs in 1991-92 are estimated from the growth rates of value of output and physical unit of production between 1983-84 and 1991-92. In case of agriculture the sectoral estimates of output are based on the projected output levels of 1991-92. In case of manufacturing sector, only the values of commodities are available. These values of commodities at 1983-84 prices are converted into base year price levels using the rise in price index between 1983-84 and 1991-92. Then, the real growth rates of output between 1983-84 and 1991-92 are obtained. These growth rates in real terms are used to estimate the output levels in manufacturing sector in 1991-92. In case of construction and services sectors for which output levels are not available the growth rates in real terms have been obtained on the basis of past trends of value added and output. The sectoral output in the input output table of 1983-84 are then converted into 1991-92 levels on the application of value added to output ratios in conjunction with the growth in output during the period 1983-84 to 1991-92. These estimates of output for 1991-92 are balanced with the forecast estimates of the output levels of 1991-92 obtained on the basis of actual observations until 1989-90 and forecast estimates for the period 1989-90 to 1991-92.

c) Value Added

The estimates of gross value added are available by 14 sector classification in the National Accounts Statistics. The base year estimates of gross value added in the input output model have been worked out on the basis of sectoral value added contained in the input output table of 1983-84. The value added estimates in the input output table are first aggregated to 14 sector classification of the national accounts. These are converted into 1991-92 prices using sectoral GDP deflators obtained by regressing the time series data of GDP deflators on the wholesale price index. The sectoral GDP deflators are estimated from the National Accounts Statistics. The wholesale price index for each sector has been estimated by aggregating the wholesale price index of more than 400 commodities, which are available from the Office of the Economic Adviser, Ministry of Industry Government of India. The sectoral value added in 1991-92 are forecast estimates based on the actuals until 1989-90. These estimates of gross value added in 1991-92 are used as controls to balance the sectoral estimates of value added in the base year. The conversion of commodity output into industry output for the base year has been made with the help of a "make matrix" for 1983-84. It means that the 'make matrix" of 1983-84 has been assumed to be valid for the production structure of 1991-92.

d) Final Demand Vectors

The final demand vectors consist of private and public consumption, gross fixed investment, changes in stocks, export and import vectors. The method of generation of each of these vectors is discussed below.

i) Private Consumption

The private consumption expenditure for 1991-92 is estimated first by commodity groups following the sector classification of the National Accounts Statistics. These are then disaggregated using the consumption model which generates the

3

private consumption vector for the base year at purchaser's price in conformity with the aggregate private consumption as given in the macro economic balance. The aggregate private consumption in the macro balance is bifurcated into rural and urban segments using per capita consumption differential between rural and urban areas. The private consumption vector is estimated separately for people below and above the poverty line in rural and urban areas on the basis of poverty cut off points in each area determined outside the model. The private consumption vectors for people below and above the poverty line in rural and urban areas are estimated on the basis of a demand system consisting of a Linear Expenditure System (LES) for broad groups of commodities and a set of consumer demand functions in the form of Engel equations for disaggregated commodity levels. The private consumption vector of each of these four groups of population are added to obtain the private consumption for the entire population.

This vector of private consumption is obtained at purchaser's prices. It is converted into market prices using trade and transport margin rates which are estimated outside the model. The sectoral private consumption at purchaser's prices are converted into market prices using a set of equations as described below.

Defining

C_i = Private consumption of sector i of the input output table at purchaser's price i = 1 60

C_i^* = Private consumption of sector i of the input output table at market prices i = 1 60

i = 1 60 are the 60 sectors of input output model

T_k = Margin rates with k where

k = 1 = Trade margin rates

= 2 = Railway transport margin rates

= 3 = Other transport margin rates

For the 60 sectors of input output model

i) for i = 1 2   55 58 60

$$C^* = C \ (1 \ \Sigma_{k=1}^{3} \ T_k \ )$$

ii) for i = 56

$$C_i^* = C + \Sigma_{j=1}^{60} \ C_j \ T_{2j}$$

iii) for i = 57

$$C_i^* = C_i + \Sigma_{i=1}^{60} \ C_j \ T_{3i}$$

iv) for i = 59

4

$$C_i^* = C_i + \Sigma_{i=1}^{60} C_j T_{1i}$$

"Purchasers price" and "market price" are defined as below:

i) Purchasers price (PP) = The price at which consumers buy from the market or the price at which the commodity is sold at the market.

ii) Market price (MP) = Purchasers price less trade and transport margin.

It means market price is equivalent to purchaser price less trade and transport margin of the commodity.

iii) Factor Cost (FC) = Market price less all indirect taxes net of subsidies.

It means factor cost is equivalent to market price minus all indirect taxes (i.e., taxes on central excise, sales tax, customs duties, etc.) less subsidies.

ii) Public Consumption

The public consumption or Government consumption refers to the expenditure on the current needs of the administrative departments of Central and State Governments and various local bodies and it excludes expenditure on capital formation. The aggregate public consumption expenditure is obtained from the macro- model. The commodity composition of this aggregate consumption expenditure (i.e., the Government consumption vector) is obtained by using the commodity composition as reflected in the input-output table of 1983-84 appropriately adjusted for variation in prices and checking it against the trend analysis of time series data on different components of public consumption.

iii) Gross Fixed Investment

The aggregate gross fixed investment for the base year of the Plan is obtained from the macro economic balance. As the sectoral composition of gross fixed investment is limited to a very few items, the aggregate investment is decomposed into 60 sectors of the input-output table on the basis of the sectoral share of fixed investment in 1983-84 as reflected in the input output table of 1983-84, duly adjusted for variation in prices. The estimates of capital goods delivered by different sectors have also been computed separately based on trend analysis of relevant data for the purpose of finalising the vector of gross fixed investment for 1991-92.

iv) Change in Stocks

The estimates of changes in stocks are obtained in the following way.

The estimate of aggregate of final uses, i e , final demands plus intermediate uses is obtained for each sector of input-output table The difference between the aggregate final use and supply (production plus import) of the commodity is attributed to changes in stocks. The level of inventory holding in case of certain agricultural commodities such as foodgrains, which are directly available are also taken into account while arriving at the changes in stocks. The total of changes in stock in all sectors is then checked against the corresponding figure obtained from the macro-balance.

v) Exports

Given the aggregate level of exports from macro-balance, the estimate of exports of different commodities are made on the basis of a detailed analysis of the

trade statistics available from the Directorate General of Commercial Intelligence and Statistics (DGCI&S) and the Reserve Bank of India (RBI) The Report of the Working Group on Balance of Payments (constituted by the Planning Commission for the Eighth Five Year Plan) has also been used The available data on invisibles are utilised to determine the service component of exports The value of export for each of the input output sectors is first estimated at f o b prices and then it is converted into market prices using relevant sectoral trade and transport margin rates estimated exogenously The conversion of sectoral exports from f o b to market prices are made in the following way

Defining

E_i = Export of sector i at f o b prices

E_i^* = Export of sector i at market prices

i = 1 60 are the 60 sectors of input output model

T_k = Margin rates with k where

k = 1 = Trade margin rates

= 2 = Railway transport margin rates

= 3 = Other transport margin rates

For the 60 sectors of input output model

i) for i = 1 2   55 58 60

$$E_i^* = E \ (1 \ \Sigma_k^3 \ _1 \ T_k \ )$$

ii) for i = 56

$$E_i^* = E + \Sigma_j^{60} \ _1 \ E_j \ T_{2j}$$

iii) for i = 57

$$E^* = E + \Sigma^{60} \ _1 \ E_j \ T_3$$

iv) for i = 59

$$E^* = E + \Sigma^{60} \ _1 \ E_j \ T_1$$

vi) Imports

The value of import of goods and non factor services in the base year of the plan is obtained from the macro economic balance The estimates of sectoral composition of import for the base year at current prices are obtained from the data on actual import in terms of value and quantity available from DGCI&S the Reserve Bank of India and Working Group on Balance of Payments constituted by the Planning Commission for the Eighth Plan

6

e) Input-Output Table for Base Year

The input output matrix for 1983 84 has been published by the Central Statistical Organisation Its dimension is 115 x 115 sectors These 115 sectors have been aggregated into 60 sectors for constructing an input output matrix for the purpose of the Eighth Plan exercise The basic input output table of 1983 84 represents the technology and product mix of that year at the prices prevailing in 1983 84 This table has been updated for the base year of the plan after appropriate adjustments in prices and macro economic variables The method of updating is described below

The sectoral intermediate demands are the row totals of inter industry flows in the input-output table These are also obtained by subtracting the final demand from the corresponding gross value of output The column totals of the inter industry flow matrix give the total value of input use in an industry which can also be described as the difference between gross value of output and gross value added On the assumptions that the industry s share of production in 1983 84 for each domestically produced commodity is maintained irrespective of the levels of commodity production the industry wise output levels for the base year are estimated using (a) the output coefficient matrix which is also known as make matrix and (b) the commodity output level of the 60 sectors of input output table in 1991 92 The column control total for the input matrix for the base year of the plan at current prices for each industry sector has been obtained as a difference between the gross output and gross value added of the sector The flow matrix of the base year of the plan is finally set after balancing on the basis of RAS method using the above mentioned row and column totals as control variables The aggregate intermediate use which is obtained as row totals of inter in dustry flows are compared with the control totals of the rows of the input output table The difference between the two are scanned with the help of the latest information mainly on technological changes The aggregate input use in each sector is compared with its column control total The difference between the two is reconciled allowing for some difference on the ground of technological changes that have taken place between 1983 84 and 1991 92 and for which adequate information is available The input output coefficients in certain sectors which are known to have altered between 1983 84 and 1991 92 have been estimated exogenously and are excl ded fiom the adjustment process of the matrix through RAS balancing The i ut n it ix which is balanced at market prices is converted into a matrix at factor costs using appropriate indirect tax rates of each sector

f) Import Matrix

The import matrix cons sts of a technology matr x and the import content of final demand of each sector The technology matrix embodies the import content of the product which is worked out on the basis of import intensity of the product by 60 sectors of the input output table The import content of the final demand of each sector is estimated separately for public and private consumption and for gross fixed invest ment The import flows of these two segments of import matrix i e for the intermediate use and final demand are then balanced alongwith the flows of domestic component of the input output table of the base year of the plan at market prices No distinction is made between competitive and non competitive imports

g) Indirect Tax Matrix

The import duty on private and public consumption and on gross fixed investment is estimated by applying the import duty rates on import content of the associated demand The domestic component of demand is obtained by subtracting the import content of demand from total demand Then remaining indirect tax rates are applied to domestic component of demand to obta n the domest c taxes on the above three final demand vectors i e public and private consumption and gross fixed investment Taxes on exports are estimated on application of export duty rates on export vector The estimates are made for each input output sector of the final demand vectors

7

The import duty matrix is generated from the import duty in each sector and the import content of the product. The inter industry flow matrix for the economy is then decomposed into domestic matrix and import matrix. The remaining indirect tax rates are applied to domestic matrix. The taxes on inputs are obtained as the column sum of import duty matrix and remaining indirect tax matrix. The domestic component of final demand vectors are obtained by subtracting the import content from the total demand for private and public consumption and gross fixed investment.

The inter industry transactions matrix is an aggregation of two mutually exclusive matrices i e the domestic matrix and the import matrix. The domestic matrix may be carved out by subtracting the import matrix (alongwith import duty) from the balanced input-output matrix of the base year at current prices. The indirect tax and final demand for public and private consumption gross fixed investment and exports are estimated separately from the import duty and remaining indirect tax. The components of import duties in the indirect tax matrix have been generated by applying independently estimated import duty rates on the import matrix. In a similar way the export duty rates estimated outside the model have been applied to the export vector. The remaining indirect tax rates have been applied to the domestic matrix to get the remaining indirect taxes. The sum of these three components of taxes constitute the indirect tax matrix. This is subtracted from the balanced input output table at market prices to generate the input output table for the base year at ex factory prices.

h) Input Output Coefficients for Terminal Year

The input output coefficient matrix for the terminal year of the plan is projected from the coefficient matrix of the base year after incorporating the anticipated changes in product and technology mix on the basis of information available for various sectors/industries in the economy.

The demand for import in the terminal year has been estimated separately in respect of intermediate use private consumption public consumption and investment. The import demand arising from intermediate use has been estimated for each sector on the basis of the import coefficient matrix. The import demand arising from private consumption in the terminal year has been estimated from the coefficient of import to total private consumption in the base year given the projected sectoral private consumption in the terminal year. Same method is used for estimating import demand for public consumption and gross fixed investment in the terminal year. The import coefficients have been changed in specific sectors in the light of the material balances worked out by various Working Groups consistituted by the Planning Commission and also taking into account the possibility of import substitution. It may be noted that any change in the import coefficient has been matched by corresponding change in the domestic component of the demand so as to ensure that the technical coefficients are consistent.

III Investment Model

The investment model estimates the investment requirements for a desired level of output and converts investment by destination into investment by origin or source. An econometric simulation model has been used to estimate investment by destination. The estimated investments by destination are converted into "investment by source with the help of a capital coefficient matrix. Then these are dovetailed with the input output model to ensure consistency.

The estimation of investment by destination for the Eighth Plan exercise has been made for broad aggregate sectors due to data constraints. Sectoral allocation of investment is determined by postulating investment functions. Aggregate gross investment in a sector consists of new investment and replacement investment. New investments are geared to capacity creation. The replacement investments are decomposed into 'pure replacement and modernisation. Sectoral investment is again divided into committed investment for on going projects and investment for projects

8

initiated during the plan period. Investment to output relations have a gestation lag as investments are spread over a number of years before a project or programme starts generating output.

Investment requirements consistent with a particular growth scenerio can be worked out for the plan period as a whole by sectors and in aggregate. The sectoral investment functions are estimated from distributed lag model taking into account the activity specific distribution of investment and gestation between investment and output of the sector. At the same time, incremental capital-output ratios (ICOR) are estimated for each sector on the basis of time series or cross section data on investment and incremental output, utilising production function approach in a conventional manner. Investment is also related to output with endogenously determined lag on the assumption of uniform spread of total investment over the plan period. The feasibility of the estimate of ICOR obtained from econometric exercises are assessed in the light of the ICOR estimated from the past data using conventional method i.e. dividing investment by incremental value added and projecting these for the future. The investment estimates derived from econometric estimation of the parameters of ICOR are changed in the light of productivity improvements possibly resulting from specific policy measures, or technological, engineering and organisational measures.

The parameters of the investment functions utilised in the investment model have been estimated by relating investment to incremental output with appropriate lag structure. The lag structure for each sector has been obtained from regressions fitted to the annual data on investment and output for the period 1973-74 to 1989-90.

Since the model operates with lags, and the lags in some sectors exceed the plan period, the estimation of investment during the Eighth Plan depends on the output in the post Eighth Plan period. Because of data constraints, it has been assumed that total investment is distributed equally over the gestation period. On this assumption the sectoral invesment functions are estimated from the time series data on domestic capital formation at market prices and gross value added at factor cost (both at constant prices) for 11 broad sectors. These are used to estimate investment for 60 sectors of the input-output model using the base period investment of these 11 sectors. These ICORs are used to determine the sectoral investment necessary to generate a desired output level. Investment by destination are converted into investment by source, i.e., by production activities, with the help of capital coefficient matrix, constructed from the data on capital formation by type of assets. The asset composition is framed under construction, machinery and equipment and inventory holdings or stocks. The potential effect of alternate allocation of investment by destination on sectoral growth rate is measured. Then, these are dovetailed into the input-output model to check their consistency. In case of a mismatch between availability of resources and resource requirements for investment, the requirements are adjusted and the shock is absorbed by the growth rate in post terminal year of the Plan. The investment model also generates investment by broad categories of assets, for example, construction, machinery and equipment, and changes in stocks. The model treats public and private investments separately as allocation of investment in public sector is a target while that in private sector is an indicative forecast. The model also categorises investments into replacement, modernisation and new investment. Finally, it checks the consistency of output requirements in the post-plan period with long term objectives and matches it with the growth potentials of the Plan.

The incremental capital output ratios have been estimated for 11 broad sectors, classifying investment into replacement investment, induced fixed investment including inventories and autonomous investment. The share of replacement and induced investment in total investment is decided on the basis of observed relations in the past. The investment requirements for generating a given level of capacity is known as induced investment. The creation of capacity output is determined from the incre-

mental capital output ratios with appropriate distributive lags using the time series data on investment and incremental output

The capital co efficient matrix used in the investment model to convert investment by destination to investment by source is originally estimated for 1983-84 by CSO This has been converted into base year of the plan period and at 1991-92 prices The capital co efficients differ inter sectorally and inter temporally during the time horizon of the gestation period The capital coefficient matrix of 1991 92 has been used for projections

IV The Sub Models

A family of sub models have been developed in order to evaluate a number of critical parameters most of which are extraneous to the core model

a) Sub-Model Agriculture

The agricultural sub model is developed to determine the feasibility of output targets for each sector within agriculture consistent with the type of land use in terms of irrigation seed and fertilisers The area under cultivation in association with the cropping pattern and consequently cropping intensity are assessed at a detailed regional and crop level The demand supply balance at such disaggregated level which is very essential for ensuring consistency in the medium term and which cannot be appropriately tackled by the input output model is ensured in the agricultural sub-model The parameters relating to cropping intensity area under irrigation and rainfed crops as well as area under high yielding and traditional variety of seeds by major crops at regional level are measured through the agricultural sub model developed especially for this purpose The Plan objectives of growth and diversification of agriculture self sufficiency in food and generation of surpluses for exports can adequately be assessed through the parameters estimated in the agricultural sub model in conjunction with the input output model For example the private consumption demand for food-grains as independently estimated by the consumption sub model using consumer demand function and Linear Expenditure System are matched with the foodgrains supply from the input output model

b) Sub Model Consumption

The consumption model estimates the demand for different goods and services for private consumption It takes into account the growth pattern of the economy postulated in the Plan a projected growth in population and its rural urban composition and the inequality in consumption distribution

The private consumption is divided into four segments rural and urban each into below and above the poverty line i e for poor and non poor group of population The decomposition of aggregate private consumption into rural and urban segments is done on the basis of likely estimates of population in the two segments and the per capita consumption expenditure differential between the two The private consumption in rural and urban areas are again separated for poor and non poor groups of population on the basis of exogenously determined poverty cut off point and on the assumption that monthly per capita expenditure within each area (rural or urban) follow a log normal distribution The inequality parameter of the log normal distribution is initially adopted from the National Sample Survey (NSS) data on consumer expenditure distribution of the latest year (1987 88) and then these are changed in the light of the likely redistribution during the plan period A detailed modelling is done for assessment of the poverty cut off point and the pattern of distribution of consumption for poor and non poor The consumption basket estimated through the consumption sub model is dovetailed with the input output model to ensure supply demand balances

The concept of poverty line is quantified by the Task Force on Projection of Minimum Needs and Effective Consumption Demand set up by the Planning

Commission in the Sixth Plan The poverty line estimated by the Task Force are updated for use in later years following the methodology recommended by the Study Group on the Concepts and Estimation of Poverty Line set up during the Seventh Plan The increase in price of consumption goods as reflected in the private consumption deflator of the CSO are used to update the poverty line at 1991-92 prices for use in the Eighth Plan The same deflator has been used to update the poverty line in urban and rural areas which implicitly meant that changes in prices of goods particularly consumed by the poor have remained the same in the two areas

The sectoral private consumption used in the input output model is estimated through a two stage nested behaviouristic consumption model This model comprises a Linear Expenditure System (LES) for broad groups of commodities and a set of best fitting Engel curves for items of consumption within each broad commodity LES Group This two-stage procedure results in a consumption vector compatible with 60 sectors of the input output model The aggregate private consumption derived from the macro model is used in this model LES which is a complete consumer demand system is estimated separately in rural and urban areas and within each area separately for population below and above poverty line using the time series of cross section data obtained from various Rounds of the National Sample Survey on household consumption expenditure Alternative forms of functions are tried separately for poor and non poor group of population within rural and urban areas in order to choose the best fitting Engel curve for each commodity by applying single equation weighted least squares method to the cross section data on household consumption expenditure The percentage of population in the different expenditure groups are used as weights to estimate the different forms of function

c) Sub Model Industry

The feasibility of output targets in industrial sectors obtained from the input output model are assessed with the help of material balance approach Sectoral estimates of capacity and output alongwith likely absorption of the commodity in major consuming sectors are worked out at a disaggregated level The estimates of output are worked out in physical units and the sectors here consist of homogenous products i e a homogenous commodity

The material balance approach has remained an essential tool in the determination of feasibilities of output projection The input output sectors mostly consist of a group of non homogenous products whereas the material balance approach treats the selected homogenous products

The input output model estimates sectoral output in the terminal year of the plan A sector may comprise more than one commodity The commodity-wise demand and supply within each input output sector is obtained through material balance studies Econometric studies are also carried out in case of specific commodities The production targets of the commodities within a sector are set in such a way that their aggregate growth rate is in conformity with that of the input output sector comprising these commodities

In this method the demand for a specific commodity mainly used as intermediate product is arrived at by the application of end use analysis The successive stages are

(i) identification of major consuming sectors and their sub sectors their current production and targets of production in the Plan

(ii) determination of input norms in the past on the basis of observed data and adopting these for future period in the light of relevant technical information

11

(iii) calculation of meterial requirements from the targets of production of user sector and the input norms and

(iv) estimation of addition to stocks and other uses

Material balances are prepared for key products such as coal electricity petroleum products steel heavy machinery and petro chemicals sugar cloth cotton jute non ferrous metals etc

d) Sub Model   Trade

The sub model on trade works out the projections for exports imports and current account balance in the base and terminal year of the Plan The aggregate level of exports are made consistent with the sectoral estimates of exports in the trade model A similar method is applied for imports with the difference that the sectoral imports obtained in the trade model are likely to undergo a change in the light of the inter relationship implicit in import coefficient matrix which forms a part of the input out put system The sectoral imports and exports arrived at from the input output model are suitably adjusted in the light of the parameters relating to import elasticity export elasticity changes in terms of trade set in the trade sub model The phasing of import export invisibles and current account deficit during the five years of the Plan are obtained in the core model These are checked for feasibility in the light of the information obtained in trade sub model and then finally aggregated to arrive at the aggregates of imports exports invisibles and current account deficits for the five years of the Plan

An import coefficient matrix compatible with the input output table has been generated based on the past data on use of imported inputs into the product and other technical data available in the Working Group Report on Balance of Payments constituted by the Planning Commission for the Eighth Plan Import for each sector is estimated separately for intermediate uses consumption and investment The projection of sectoral imports and exports for the plan period are made on the basis of simulation exercises treating policy packages as exogenous The choice between alternative import allocation and export target and their effect on balance of payments and overall rate of economic growth are explored from simulation exercises

e) Sub Model Financial Resources

The estimation of domestic savings separately for public and private sector and the financing of investment requirement in plan are assessed from a host of inter related variables in the financial resources sub model Inter sectoral flow of funds are also worked out in the financial resources sub model The savings in the public sector are estimated separately for Government sector and public enterprises in the framework of national acounts The savings of Government sector are assessed from a detailed analysis of various components of income such as direct and indirect taxes non tax revenues and public expenditure such as debt servicing and subsidies The savings of public sector enterprises are assessed from the enterprise level analysis of their operational performance evaluated in terms of return to investment and retained profits The savings of private sector is assessed separately for private corporate sector co operative sector and household sector The savings behaviour of the household sector has been related to disposable income and price inflation The composition of savings has been disaggregated into currency deposits small savings provident funds and corporate securities Finally the inflow of foreign savings including invisibles are obtained from the estimate of the Reserve Bank of India and the Ministry of Finance These are integrated under the frame of public sector plan outlay and its pattern of financing

The scheme of financing pattern of public sector plan consist of budgetary support to the plan and internal and extra budgetary resources (IEBR) of public enterprises This is backed up by inflow of foreign savings The inter sectoral

flow of funds in terms of flow of household savings to public sector is worked out from an analysis of the financing system embracing the structure of interest rates and other monetary and financial variables which govern the relative rates of return in public and private enterprises

The financial resources sub-model estimates the availability of resources in order to finance the investment needs estimated in the input-output and investment model, which is necessary to generate the desired growth rate. This estimate of resource in the financial resources sub-model is procedurally recursive to the input-output cum investment model due to the simultaneity between savings and income

V) Structure of Output and Value Added

The sectoral growth rates of value added and gross output obtained from the multi-sectoral input-output-cum-investment planning model are given in Table-1 1 The growth rates in gross output are generally found to exceed the growth rate in value added as a result of the rise in the ratio of input to output within the sector. The structure of value added and output as a result of the growth scenario are given in Table-1 2 The share of sectoral output in total output for the base and the terminal year of the plan shows a shift in the structure of output from primary to secondary and tertiary sectors

Sectoral investment allocations consistent with the sectoral output profile are given in Table-1 3 The pattern of investment shows a significant shift of investment in favour of agriculture and allied activities to 18 64 per cent of total investment in the Eighth Plan (1992-97) The results also show that the above increase in investment in agriculture sector has not altered the relative share of investment in infrastructure sector

VI) The Perspective Plan

The Eighth Plan has been formulated against the background of a perspective covering the period of 15 years from 1991-92 to 2006-07 The perspective of development visualises elimination of poverty and unemployment a minimum level of food consumption reduction in disparity between urban and rural areas in respect of income and consumption and meeting the basic socio ecoomic needs and aspirations of the people The factors which basically influence the scenario of the perspective plan are demographic trends and basic resource endowments The structure of growth of the population and the associated growth and size of the labour force characterize the demographic trends Basic resource endowments are assessed from land water energy and other essential minerals and environment

The output level of the terminal year of the Eighth Plan serves as the base for projections of growth in the future The sectoral production levels in the perspective period are estimated from the input output model on the basis of exogenously estimated values of the macro variables keeping the base level technology co-efficient matrix and other associated parameters generally unchanged The results show that acceleration in the rate of economic growth is an essential pre-requisite for realisation of the objectives set out in the perspective period The choice of growth path is confronted with a trade-off between faster growth in the plan period and somewhat slower growth in the post plan period In the background of initial capacity constraints the feasible growth rate consistent with the long run projection of sectoral demand was set at 5 6% per year for the plan period and 6 2% per year in the post plan period The pattern of long term growth in the perspective period is thus consistent with the investment policy framed in the plan keeping in view the socio economic requirements of the population The growth rate in the post plan period estimated as 6 2 per cent per year was revised marginally upwards to 6 28 per cent considering related improvements in efficiency in key areas and institutional reforms The model results are based on an

13

exogenously determined savings rate of 23 9 per cent and investment rate of 24 9% in the post terminal period

The demand requirements in the perspective period are critically based on the target to eliminate poverty This would necessitate increase in income particularly of the poor and availability of foodgrains The increase in per capita consumption of the people particularly of those in the poor group would make a draft on foodgrains demand Thus the foodgrains requirements in the year 2006 07 on the basis of growth of population and income are estimated at 283 million tonnes Total consumption is projected to rise at the rate of 5 9% per year during the post terminal period The major indicators of development for the perspective period are given in Table 1 4

The basic data used to run the model as well as some of the detailed results by 60 sectors of the input output model are given in Annexure Tables 1 1 to 1 25 It gives for base and terminal year of the plan the matrices of caliberated input output coefficients value of inter industry use and final demands the import coefficients and import transactions The annexure tables also give the structure of final demand the structure of imports in final demand and the structure of indirect taxes The output coefficient and the capital coefficient matrix are also given in the annexure The mathematical scaffolding of the model is described below

Mathematical Scaffolding of Eighth Five Year Plan

The quantitative framework of the Eighth Plan consists of a core model and several sub models. The core model consists of macro model, input-output model and investment planning model. The sub models which are primarily designed to supply the inputs to the core model exogeneously are developed in the areas of agriculture, industry, consumption, trade, financial resources and demography and employment.

1. Macro-Economic Model

The macro-economic model estimates the scalar values of the macro variables such as income, measured by Gross Domestic Product at factor cost, Indirect Taxes, GDP at market prices, Gross National Product, Savings, Disposable Income for base and terminal year, including values of variables such as Exports, Imports, Public and Private Consumption, and Investment. The model can be conceived in the form of a set of structural equations most of which are based on income and expenditure identities. Some of the variables and parameters used in the macro model are either exogeneously determined or are obtained from other sub-models.

Target growth of the economy is determined from the assessment of macro economic aggregates such as consumption savings investment and net inflow from the rest of the world. The values of the macro variables are set by balancing income and expenditure for a number of alternative growth rates using simulation exercise based on econometric modelling. The set which is consistent with the aggregate savings behaviour and domestic production supply possibilities is adopted.

The base year (1991-92) GDP at factor cost along with the targetted rate of growth of Plan determines the GDP at factor cost of the terminal year (1996-97)

$$Y^t = Y^0 (1 + \bar{r})^5 \qquad (1.1)$$

Y^t = Aggregate GDP at factor cost in the terminal year (t)
Y^0 = Aggregate GDP at factor cost in the base year (0)
$\bar{r}$ = Targetted annual rate of growth of GDP at factor cost

The GDP at factor cost and the net indirect taxes estimated by the Financial resources sub-model gives the GDP at market price

$$Y^t_M = Y^t + TTX^{*t} \qquad (1.2)$$

Y^t_M = Aggregate GDP at market price in the year t
TTX^{*t} = Total Indirect Taxes in the year t

GNP is the sum of GDP at market prices and net factor income from abroad

$$GNP^t = Y^t_M + NFI^{*t} \qquad (1.3)$$

GNP^t = Aggregate GNP at market price in year t
NFI^{*t} = Net Factor Income from Abroad in year t

Domestic savings are estimated exogenously and gross investment is defined as the sum of domestic savings and net imports of goods and non-factor services less net factor income from abroad and other current transfers from the rest of the world

$$INVS^t = SAV^{*t} + NIMP^t - NINV^{*t} \qquad (1.4)$$

15

$INVS^t$ = Gross Investment at Market Prices in year t
SAV^t = Gross Savings at Market Prices in year t

Exports are exogeneously determined by the Trade Sub-model Imports are also estimated exogenously in the Trade Model and are incorporated in the macro-model An alternative estimate of imports is determined in the input-output model The estimate of imports from the input-output model is made consistent with the import estimate from the trade cum macro model through a controlled parameter By definition,

$$NIMP^t = M^t - E^t \qquad (1\ 5)$$

$NIMP^t$ = Net Imports in year t
M^t = Aggregate Import of Goods & Non-Factor Services in year t
E^t = Aggregate Export of Goods & Non-Factor Services in year t

$$NINV^t = NFI^t + CDY^t \qquad (1\ 6)$$

CDY^t = Other Current Transfers (Net) in year t

Disposable Income is the sum of GNP at market price and other current transfers

$$DI^t = GNP^t + CDY^t \qquad (1\ 7)$$

DI^t = Gross Disposable Income in year t

Total consumption is the difference between Disposable Income and Savings

$$TCON^t = DI^t - SAV^t \qquad (1\ 8)$$

$TCON^t$ = Total Consumption in year t

The Total Consumption is decomposed into Public and Private consumption in the macro model The decomposition is effected using an exogenously determined parameter alpha

$$PC^t = TCON^t \times alpha \qquad (1\ 9)$$

$$CM^t = TCON^t\ (1 - alpha) \qquad (1\ 10)$$

PC^t = Aggregate Public Consumption in year t
CM^t = Aggregate Private Consumption in year t
alpha = Proportion of Public Consumption to Total Consumption

The changes in stocks is derived as a proportion of Gross Investment

$$ST^t = ALFA^* \times INVS^t \qquad (1\ 11)$$

$ALFA^*$ = Proportion of Changes in Stocks in Gross Investment
ST^t = Aggregate Changes in Stocks in year t

Gross fixed investment is the difference between investment and changes in stocks

$$FAC^t = INVS^t - ST^t \qquad (1\ 12)$$

FAC^t = Gross Fixed Investment market price year t

The model iterations begin with an initialised value of investment. The above income and expenditure identities in combination with the input-output model endogenously determine investment in the terminal year of the plan. The link between macro model and input-output model is established by aggregate imports and the process of iteration between these two models begins. The iterative process ends when the investment in the terminal year is obtained as the same value given in the macro model. Investment model is run to derive investment requirement at broad aggregate sectors. Then investment by destination is converted into investment by origin. The mismatch between the availability of investment and requirement of investment is removed by adjusting the post terminal growth rate.

2. Input-Output Model

The input-output model is used to derive mutually consistent sectoral output and corresponding sectoral investments and other final demands. The final demand vectors (at the 60 sector level) of consumption and exports are exogenous and the remaining final demand vectors are determined in the input-output model.

Changes in Stock

$$ST_i^t = s_i \ (X_i^t - X_i^0) \ ST^t / \Sigma \ s_i \ (X_i^t - X_i^0) \ \dots\dots(2.1)$$

ST_i^t = Sectoral Changes in Stocks in year t.

s_i = Sectoral Changes in Stocks Coefficients.

X_i^t = Output of Sector i at factor cost, year t.

X_i^0 = Output of Sector i at factor cost, year 0

Public Consumption

$$PC_i^t = b_i \ x \ PC^t \ \dots\dots(2.2)$$

PC_i^t = Public Consumption of Sector i in year t.

b_i = Share of i-th Sector in Public Consumption

$$\text{Here,} \quad \begin{matrix} 60 \\ \Sigma \ b_i = 1 \\ i = 1 \end{matrix}$$

Gross Fixed Investment

$$GFM_i^t = P_i \ x \ FAC^t \ \dots\dots(2.3)$$

GFM_i^t = Gross Fixed Investment, Sector i, at market price, year t.

P_i = Proportion of Gross Fixed Investment originating from Sector i

$$\text{Here,} \quad \begin{matrix} 60 \\ \Sigma \ P_i = 1 \\ i=1 \end{matrix}$$

Imports

The imports are determined as sum total of import contents of intermediate use and of final demands. The demand for imports arising from inter-industry use is estimated using the import coefficient matrix. The demand for imports for final use is estimated from the import content of the various component of final consumption.

$$MS_i^t = \Sigma_j \ a_{ij}^{tm} \ X_j^t + CM_i^t + GM_i^t + GFIM_i^t \ \dots\dots(2.4)$$

17

$$\text{where, } M^t = \sum_i MS^t_i \qquad (2\ 5)$$

MS^t_i = Total Imports of Sector i, year t

a^{tm}_{ij} = Imported inputs of Sector i per unit of output of Sector j, year t (Commodity x Commodity Matrix)

X^t_j = Industry output of Sector j, year t

$\sum_j a^{tm}_{ij} X^t_j$ = Import requirement for intermediate use

$$GM^t_i = h_i \times PC^t_i \qquad (2\ 6)$$

GM^t_i = Import content of Public Consumption, Sector i, year t

h_i = Import coefficient of Public consumption, Sector i

$$GFIM^t_i = m_i \times GFM^t_i \qquad (2\ 7)$$

$GFIM^t_i$ = Import content of Fixed Investment , Sector i, year t

m_i = Proportion of Imported Fixed Investment to Total Fixed Investment, Sector i

GFM^t_i = Gross Fixed Investment at Market Price, Sector i year t

$$CM^t_i = C_i \times CMP^t_i \qquad (2\ 8)$$

CM^t_i = Import content of Private Consumption, Sector i, year t

C_i = Proportion of Imported Private Consumption to Total Private Consumption, Sector i

CMP^t_i = Private Consumption at Market Price Sector i year t

Conversion from Market Price to Factor Cost

The final demand vectors at market prices are converted into factor cost on application of indirect tax rates

Public Consumption

$$G^t_i = GM^t_i + (PC^t_i - GM^t_i - n_i \times GM^t_i) / (1 + t_i) \qquad (2\ 9)$$

G^t_i = Public Consumption of Sector i at Factor Cost year t

t_i = Other Indirect Taxes per unit Value of Output, Sector i

n_i = Import Duties per unit Value of Imports, Sector i

Exports

$$E^t_i = (1 - e_i) \times EMP^t_i \qquad (2\ 10)$$

E^t_i = Exports of Sector i at Factor Cost year t

e_i = Export Duty per unit Value of Exports Sector i

EMP^t_i = Exports at Market Prices Sector i, year t

Gross Fixed Investment

$$GF^t_i = GFIM^t_i + GFM^t_i / (1 + t_i) - (1 + n_i) \; GFIM^t_i / (1 + t_i) \qquad (2\ 11) \quad 11)$$

GF^t_i = Gross Fixed Investment, Sector i, at Factor Cost, year t

Private Consumption

$$C_i^t = CM_i^t + [\ CMP_i^t - (1+n_i)\ CM_i^t\ ] / (1 + t_i)\ ......(2.12)$$

C_i^t = Private Consumption at Factor Cost, Sector i,year t.

Total Indirect Taxes (Net)

The difference between the aggregates of various final demand components at market price and at factor cost produces the estimates of the respective components of net indirect taxes.

$$TGX^t = PC^t - \sum_i\ G_i^t\ ....(2.13)$$

TGX^t = Indirect Tax (including import duty) on Public Consumption, year t

$$TIX^t = FAC^t - \sum_i\ GFI_i^t\ ....(2.14)$$

TIX^t = Indirect Tax (including import duty) on Gross Fixed Investment, year t.

$$TCX^t = CM^t - \sum_i\ C_i^t\ .....(2.15)$$

TCX^t = Indirect Tax (including import duty) on Private Consumption, year t.

$$TEX^t = EMP^t - \sum_i\ E_i^t\ .....(2.16)$$

TEX^t = Export Duty

The indirect taxes on intermediate use are estimated as

$$TINX^t = \sum_{i=1}^{60}\sum_{j=1}^{60}\ (aij^t - aij^{tm})\ X_j^t\ t_i\ + \sum_{i=1}^{60}\sum_{j=1}^{60}\ aij^{tm}\ X_j^t\ n_i\ ....(2.17)$$

$TINX^t$ = Total Indirect Taxes on Inputs in year t.
aij^t = Inputs of Sector i per unit of Sector j, year t (Commodity x Commodity Matrix).

The total (net) indirect taxes is the sum of indirect taxes on inputs and indirect taxes on various components of final use.

$$TTX^t = TINX^t + TCX^t + TGX^t + TIX^t + TEX^t\ .....(2.18)$$

TTX^t = Total (Net) Indirect Taxes in year t.

The estimate of total (net) indirect taxes from the input-output model is made compatible with that estimated in the macro model using iterative procedure.

Output

The sectoral ouput levels, consistent with the demands from final uses, are projected by the input-output model as sum total of intermediate uses and final demands thereby ensuring a consistency between the different sectors in output structure.

19

$$X_i^t = \sum_j a_{ij}^t \, X_j^t + C_i^t + G_i^t + GF_i^t + ST_i^t + E_i^t - MS_i^t \qquad (2\ 19)$$

The input-output model also provides sectoral profiles of input use, industry output, value added and net indirect taxes

The industry output is derived using the market share matrix (make matrix) and the commodity output vector.

$$G_j^t = \sum_j D_{ij} \, X_j^t \qquad (2\ 20)$$

G_j^t = Gross Industry Output, Sector j, year t
D_{ij} = Market Share Matrix (Make Matrix)

Value Added

The value added profile is derived by subtracting input use from the industry output

$$V_j^t = G_j^t \, [\, 1 - \sum_i b_{ij}^t \times (1 + t_i) - \sum_i b_{ij}^{tm} \times (n_i - t_i)\,] \qquad (2\ 21)$$

V_j^t = Gross Value Added Sector j year t

b_{ij}^t = Inputs of sector i, per unit of sector j, year t (Commodity x Industry Matrix)

b_{ij}^{tm} = Imported inputs of sector i, per unit of sector j year t (Commodity x Industry Matrix)

After the outputs are balanced in the input-output model, the estimated imports which provide a crucial link between the input-output model and the macro model are taken up by the macro-model for iterations with the input-output model till the investment demand in the terminal year of the plan converges to the same value in successive runs of the model   The controls are then shifted to the investment model from the macro-model

3. Investment Model

Investment requirements at broad sector levels (11 sectors) and conversion of investment by destination to investment by origin are worked out in the investment model The value added of both base and terminal year at 60 sector of input-output model are aggregated to 11 sectors of the investment model and the sectoral growth rates during the plan period are calculated These are then used for estimating investment by destination Investment Model also estimates the aggregate post-terminal growth rate consistent with the sectoral growth rates of the medium term

Post Terminal Growth Rate

The gestation lags between investment and output makes it imperative to integrate the long-term perspective with medium term This consistency between the medium term and the long term growth rates is achieved at broad 11 sector levels of the national accounting frame

A post terminal growth rate estimated iteratively also brings about consistency in estimated investment (based on sectoral medium term and post terminal growth rates) and the investment level projected by the interactions of macro model and the input output model

The post terminal growth rate is estimated with the help of iterative process. In case of a mismatch between available resources and estimated investment, the latter is adjusted and the shock is absorbed by the post terminal rate of growth. An econometric procedure is adopted for this solution. The model is non-linear in parameters and is solved using Newton-Raphson Method.

Investment Estimates:

For projecting year-wise investment by destination, an econometric simulation model has been used taking into account investment lags. This model incorporates an accelerator-type investment theory in which current demands for investment goods depend on the expected growth of output. These projections are carried out using the following equations.

$$VABB(I) = [(VT(I)/VO(I)) ** (1/YRS)] \ ....(3.1)$$

VABB(I) = Rate of growth over Plan period, 11 sectors.
VT(I) = Sectoral Value added, 11 sectors, terminal year.
VO(I) = Sectoral Value added, 11 sectors, base year.
YRS = 5

Using VABB(I) and the sectoral rate of growth of value added over the perspective period, defined as RT(I), terminal year values VITL and VITL1 are defined depending on the sectoral lags.

$$VITL = VO(I) \times (1+VABB(I))^{TL} \quad \text{if } TL < 5$$

$$VITL = VO(I) \times (1+ RT(I))^{TL-5} \quad \text{if } TL \geq 5 \ ....(3.2)$$

where TL = T+AL(I) ; T= 1, ...5

AL(I) = Lags between investment and output

$$VITL1 = VO(I) \times [1+VABB(I)]^{TL1} \quad \text{if } TL < 5$$

$$VITL1 = VO(I) \times [1+ RT(I)]^{TL1-5} \quad \text{if } TL \geq 5 \ ....(3.3)$$

where TL1 = T

A function DIFV is defined as:

$$DIFV = VITL - VITL1 \ ....(3.4)$$

Using (3.4),

$$AI(I) = AK(I) \times DIFV + AUTO(I) = PINV \ (I,J) \ .....(3.5)$$

AI(I) = Sectoral Investments for the Jth year, J = 1, 5.
AK(I) = Incremental Capital Output Ratio, 11 sectors , I= .1,11.
AUTO(I)= Autonomous Investment in Terminal year, I=1,11.

$$TS(I) = \sum_{J} PINV(I,J) \ ....(3.6)$$

TS(I) = Sectoral Gross Investment over the Plan Period, 11 Sectors

$$PT = \sum_{I} TS(I) \ ....(3.7)$$

PT = Aggregate Gross Investment over the plan period

The estimated investments by destination for the terminal year (PINV(I,5)) are converted into investment by source sectors with the use of a capital coefficient matrix

$$GFICON = \sum_I PINV(I,5) \times PCON (I) \qquad (3\ 8)$$

GFICON = Final value of gross investment in construction sector at market prices, terminal year

$$GFIMAC = \sum_I PINV (I,5) \times PMAC (I) \qquad (3\ 9)$$

GFIMAC = Final value of gross investment in machinary and equipment at market prices, terminal year

$$TSTK = \sum_I PINV (I,5) \times PSTK (I) \qquad (3\ 10)$$

TSTK = Final value of changes in stocks at market prices, terminal year

PCON(I), PMAC(I), PSTK(I) are elements of the capital coefficient matrix (11 x 3)

$$GFITOT = GFICON + GFIMAC \qquad (3\ 11)$$

GFITOT = Total Gross Fixed Investment terminal year

In the event of non-convergence i e , if there is a mis-match between availability of investment and required investment to meet the desired medium term growth rate, the controls are shifted to the input output model along with revised values of control ratios RAC RAM and RAST and PII(I) The control ratios are defined as follows

i) RAC = GFICON/GFITOT = Ratio of investment in construction to total fixed investment terminal year

ii) RAM = GFIMAC/GFITOT = Ratio of investment in machinery and equipment to total fixed investment, terminal year

iii) RAST =TSTK/TGFI = Ratio of changes in stocks to total investment, terminal year, where TGFI is aggregate gross investment in the terminal year

iv) PII(I) = Proportions of gross fixed investment in machinery and equipment for each sector (except construction) to total gross fixed investment in the terminal year However, for the construction sector,

$$PII(I) = RAC$$

$$Also \quad \sum_I PII(I) = 1$$

In effect, the investments by source sectors are dovetailed with the input-output model for sectoral consistency

Table-1.1
Growth in Value Added and Value of Output : Eighth Plan

(Percent per annum)

S.No.	Sector	Value Added	Value of Output

2 The growth rate of GDP is annual average for the period beginning 1991-92

CHAPTER-2

DEMOGRAPHY SUB-MODEL

The demographic density and spread provides the starting point of all planning exercises. Alongside population dynamics has to be explicitly assessed and its different charactensitics have to be closely considered while developing the equations for all other sub-models.

Population Projections

Population Projections for the period 1992-2007 were worked out with no major changes in methodology used for the Seventh Five Year Plan, mainly because the full results of the 1991 Census of India were yet to be released, especially the age-sex distributions; and 1991 Census results when available, showed that differences were minor. For these estimates, the year 1986 was taken as the bench-mark year and the crude birth rate (CBR), crude death rate (CDR) and growth rate (GR) for the period 1981-86 as revealed by the Sample Registration System (SRS) were considered as the base level estimates The Standing Committee of Experts on Population Projections, which met in 1988-89 finalised the projections for the period 1990-2005 on the basis of these bench-mark data. In view of the proximity of the 1991 Population Census, the Standing Committee did not make any fundamental change in the population projection methodology adopted by the Expert Committee on Population Projections. Some modifications were, however, made on the basis of the CBR, CDR and Infant Mortality Rate(IMR) figures for the period 1986-90 and also the population total, sex-ratio, percentage of urban population and work participation rates, as obtained from Census of India, 1991 and the Couple Protection Rate (CPR) of 1991. The method used is the component method of population projection, the componenets under consideration being (a) Fertility (b) Mortality and (c) Migration. The broad assumptions and methodology are discussed in the following paragraphs.

Fertility

Assumptions regarding fertility are based on the evaluated results available from administrative statistics on performance of family planning programmes in terms of likely levels of couples effectively protected in recent years and the proportion of females married, in the age group 15-44 as recorded by the 1981 Census of India.

It is assumed that the changes in the proportion of married females in the reproductive age-groups 15-29 and 30-44 observed during 1971 and 1981 will continue till the year 2007. In the age-group 15-29 a decline is assumed due to the trend of increase in the age at marriage, whereas in the age-group 30-44 an increase is assumed as it is felt that less number of widows would be likely. The observed changes in the trends for the two age-groups during 1971-81 have been linearly extrapolated for the later periods The proportion of married females in the age-group 15-44 thus worked out is presented in Table-2.1.

The Couple Protection Rates (CPR) published by the Department of Family Welfare are adjusted for quality as recommended by the Committee appointed by the Government of India in the Department of Family Welfare. The CPRs to be achieved in the future years for different States and the country as a whole are estimated by using a logistic curve connecting data available on CPR at two points of time viz., 1972 and 1987 and using more or less the same asymptotic values as used for the Seventh Plan projections. A comparative picture of the CPR values that were used for the Seventh and Eighth Plan documents is indicated in Table-2.2.

However, there has been a significant change in the formulae used for obtaining the future GMFR (General Marital Fertility Rates) values. The GMFR gives

the number of births per year per 1000 married females in the age-group 15-44 As the General Fertility Rate (GFR) defined as the number of births per year per 1000 females aged 15-44 has been estimated from the Sample Registration System (SRS) data for the period 1981-85 this period becomes the new bench mark in this exercise Fresh GMFR values could be calculated for the country as a whole and for different States for 1985 using the proportion of married females The relationship between CPR and GMFR for a period under consideration used for the Eighth Plan is consequently updated as

$$GMFR^t = \frac{1 - CPR^{t\,1}}{1 - CPR^{1984}} \cdot GMFR^{1985}$$

Using the projected CPR for the future years the GMFR values and hence the GFR values for the future years are projected

Mortality

The mortality assumptions of the Seventh Plan Demography Sub-Model have generally been kept unchanged for the Eighth Plan Starting with SRS life table of 1980 which gives an expectation of life at birth of 54 1 years for males and 54 7 year for females in 1980 an annual improvement of 0 5 years in life expectancy at birth was assumed for males till it reached a level of 60 years after which the annual increase was reduced to 0 45 years in case of females the annual gain in life expectancy at birth was assumed at 0 55 years till it reached 60 years after which the Improvement is reduced to 0 50 years per annum For the quinquennial 2001-2006, it has been assumed that expectation of life at birth for males will rise at the rate of 0 40 per annum till it reaches the age of 65 For females the annual gain has been assumed to be 0 25 per annum On this basis the expectation of life at birth for the country as a whole is 64 8 for males and 65 8 for females for the quinquennium 2001-2006 and 66 1 years for males and 67 1 years for females in 2006 2011

At the State level separate life tables for males and females are constructed for the period 1979 80/1978-80 using SRS age-specific death rates The expectation of life at birth are estimated using Greville s method Annual increase in expectation of life at birth is assumed to follow a function of the level achieved at the point of time For males it is estimated according to the pattern given in Table-2 3 whereas for females there was an additional improvement of 0 05 years per annum on the e_0^0 values

A review using the SRS death rates recorded for the period 1981-86 showed that except for Kerala and Maharashtra the assumption could be kept unchanged However for these two States it was found that the death rates recorded by SRS for the period 1981-86 are themselves much lower than those estimated on the basis of the 1978-80 rates For these two States therefore certain adjustments are done by using the survival ratios based on the life expectancy for the period 1981-86 worked out from the SRS age-specific mortality rates for the period 1981-86

Migration

Using the data on place of birth the number of persons whose place of birth was outside India was recorded from the 1971 and 1981 Census results (1991 census results on this aspect are not available) Applying the 10 year survival ratios of 0 9165 for males and 0 9122 for females on these number inter-decadal migrants into India is observed From the number of persons born in India but living abroad the number of out- migrants is also found It is observed that the net migrants as on 1981 is negligible Thus for the future years in the light of past experience, the net migration is considered to be negligible at the all-India level

On the basis of the place of last residence data and duration of residence 0-9 years, inter-state migration is observed to be slightly above 1% in the States of Bihar, Haryana, Maharashtra and Uttar Pradesh. So adjustment is made for these four states only. It is assumed that in these States the trend in migration rate observed during 1961-71 and 1971-81 would be continued in the next three decades, during 1981-2007.

Method of Projection

It is assumed that the age-specific mortality rates for males and females separately, would conform to the South Asian Model pattern of Life Table presented by the United Nations for males and females separately and these Life Tables are assumed for the end of projection period 2007. From the set of initial Life Tables 1980 and final Life Tables of 2007, values of $n^q x$'s (i.e, probability that a person aged x years does not survive till age n) for the intervening years are derived assuming that mortality would decline linearly.

From the $n^q x$ values, the e_0^0 (expectation of life at birth)-values are calculated for each of the intervening years and are made to converge to the level of e_0^0 assumed earlier in the mortality assumption by an iterative procedure. Finally, the survival ratio's for each 5 year age-group are calculated from the derived Life tables and are used to project the population for each five year age-group quinquennially.

The 0-4 age-group population for the various periods are derived by using the projected General Marital Fertility Rate (GMFR) for the quinquennium, number of married females in the age-group 15-44, survival ratio's for birth in the age-group 0-4 for males and females, and an assumed sex-ratio of 105 males to 100 females at birth. As GMFR gives the number of births per year per 1000 married females in the age-group 15-44 years, for a period "t" under consideration:

Number of births during $(t-4, t) =$

$5 \times GMFR_t \times$ (No. of married females aged 15-44)$_t$.

Using the sex-ratio (for males 105/205), the number of boys and girls born were estimated. Multiplying these by the survival rates (Infant Mortality Rates for 0-1 year and Child Mortality rates for 1-4 years, separately fcr boys and girls), the number of surviving boys and girls aged 0-4 years for the period t and hence the age-distribution and total population for the period are obtained.

The 1991 Census results show that the projected population for 1991 on 1st March, according to this method has only a slight difference of around 1.4 per cent but the number of females per 1000 males, which was expected to rise as the 1981 census showed, had again dipped. These necessitated some modifications for the post-1991 projected results for the overall total population figures. Taking the 1991 census sex-wise population base data and the growth rates as observed by using the methodology already described, the modifications are incorporated. This did not, however, imply change in the vital rates.

Age-distribution Projection

The age-distribution for the years are based on the annual estimates worked out for these years. For a period t lying in between period 1 and 6, say, (as quinquennial age-distribution are obtained by the projection methodology) a value of K is determined, such that

$$Kp_1 + (I-k) P_6 = P_t$$

where P_1, P_t and P_6 are the annual populations of period 1, t and 6 respectively   Using this constant 'k , the population $P_t(x)$ for age-group "x", is calculated as

$$P_t(x) = k \ P_1 \ (x) + (l-k) \ P_6 \ (x)$$

Single Year Age Projection

An oscillatory interpolation curve is assumed for getting the single-year age-distribution as the single year Census data will have inherent response-biases in terms of number preferences etc   An oscillatory interpolation formulae using Sprague multipliers is employed for this exercise

Rural-Urban Distribution of Population

The Standing Committee of Experts on Population Projection in 1989, on the basis of the 1981 Census results   projected for India the percentage of urban population to total to be 27 87% in 1991 with a total urban population of 235 millions This was done by projecting the Urban population in each State separately mainly by using the increasing Urban-Rural Growth Differential method (URGD) The method is based on the assumption that the urban-rural growth differential follows a logistic pattern, though the exact forms (parameter values) were different for different States The All-India urban proportion and urban total was derived by adding the projected urban population of the various States and Union Territories

However the 1991 census results have shown a much smaller sized urban population of 217 2 million which constitutes only 25 72% of the total 1991 census population This indicates 2 15% shortfall in urban proportion As this sudden fall could not be explained by the urban-rural growth differentials the urban population for the next decade 1991-2001 is projected on the basis of the average annual rate of growth observed during the last 20 year period i e 1971-91 rather than the decelerated rate of growth observed   during 1981 91 this representing the long term trend of urbanisation In the post 2001 period the rate of growth of urban population is assumed to be gradually declining in line with the assumed reduction in the rate of natural increase, though the share of urban population increases continuously

To obtain the sex-composition of rural and urban population   the size of the rural male population is first estimated It is assumed that the trend of the rural sex-ratio would be similar to that of total population for which projections by sex are already available The formulae used are

$$[R_m/R]_{1991+5r} = [R_m/R]_{1991} \ * \ [T_m/T]_{1991+5r}/[T_m/T]_{1991}$$

where r = 1,2 3 and so on

R = Rural population

T = Total population of all areas

R_m=Rural male population

T_m= Total male population of all areas

Once the rural male population are obtained by applying the above ratios to the corresponding projected rural populations the rural female population are worked out by subtraction

The age distribution of rural and urban population, sex-wise, for the 5 broad age-group viz., 0-14, 15-29, 30-44, 45-59 and 60+, as reported by the 1981 census (in the absence of the 1991 census results) are put in a 5x2 matrix form. The marginal totals were adjusted to correspond to 1981 smoothed age-data by repeated iterations (by method of difference elimination). Projections by age and sex for rural and urban areas for future years are obtained by the method of difference elimination on the 1991, 1996, 2001, 2006, 2011, urban-rural sex wise break-ups of the total population.

Labour Force Projection

Based on the recommendations of the Committee of Experts on Unemployment Estimates set up by the Planning Commission in 1969 (Dantawala Committee), the National Sample Survey Organisation (NSSO) has standardised the concepts and definitions of Labour force, employment and unemployment and the same has been adopted in quinquennial surveys on employment and unemployment since 1972-73 (27th Round). The various estimates are based on 3 concepts viz., Usual Status, Weekly Status and Daily Status.

These are explained below:

(i) Usual Status Concept

This concept refers to the usual activity status-employed or unemployed or outside labour force of those covered by the survey. Thus, the activity status is determined with reference to a period of 365 days. A person is said to be employed if he is working for a relatively longer time during the reference period and unemployed if he was available or seeking work.

(ii) Weekly Status Concept

According to this concept the activity status is determined with reference to a period of the preceding 7 days A person who reports as having worked at least for one hour on any day during the reference period of the week while pursuing a gainful occupation was deemed to be employed. A person who did not work even for one hour during the reference period but was seeking work or was available for work was deemed to be unemployed

(iii) Daily Status Concept

Here activity status of a person for each day of the preceeding 7 days is recorded. A person who worked at least for one hour but less than four hours was considered having worked for half a day. If he worked for 4 hours or more during a day, he was considered as employed for the whole day.

Labour force is estimated on the basis of usual status participation rate. Estimates of rates of labour force participation for broad age-groups for males and females, for rural and urban areas separately have been provided by the latest NSSO round on employment-unemployment during 1987-88 (43rd round). Though the earlier rounds of NSSO on employment-unemployment have shown that the labour force participation rates (LFPRs) have been decreasing, especially for males, for the projection it has been assumed that with concerted efforts during the Eighth Plan and later, the LFPRs both for males and females in rural and urban areas will increase. Further, it is expected that the LFPRs according to the three concepts described earlier, will follow an increasing trend as given in Table-2.4.

Applying these labour force participation rates to the projected population figures for the different periods, the total labour force for the periods, have been obtained for each concept separately. This also gives the number of people in the

labour force aged 5 and above It is assumed that there are no workers below the age of 5 years.

The estimates of labour force for rural and urban areas sex-wise is done using projected labour force participation rates according to the 3 concepts These participation rates have, however, been adjusted so that the totals of these categories match the total labour force figures mentioned in the previous paragraphs

For the purpose of estimating labour force for the ages 15-59 child labour rates for age-group 0-14 years and aged labour force participation rates for 60+ are obtained by repeating the calculations same as those for the specific group of population The labour force in 0-14 and 60+ is obtained from the projected age-group populations The labour force in age 15-59 group is finally obtained by subtraction The results are presented in Table-2 5

Employment Projections

The Eighth Plan aims to reduce unemployment to negligible level by the turn of the century Treating employment generation and economic growth as mutually complementary the Eighth Plan aims to generate gainful and sustainable employment through economic growth and restructuring of output composition of growth

The growth and structural change in employment during the period 1977-78 to 1987-88 assessed from the quinquennial survey of employment and unemployment by NSSO have been used to estimate the parameters relating to employment estimation in the Eighth Plan The main feature of employment growth during the period 1977-78 to 1987-88 as revealed by the NSSO surveys on employment and unemployment and given in Table-2 6 to Table-2 9 are as follows

a) Annual growth of employment has been at about 2 per cent

b) Growth rates of employment have been relatively more in urban areas as compared to rural

c) Employment of males and females has grown more or less at the same rate

d) All major sectors except agriculture experienced employment growth of more than 3 per cent per annum

e) The employment growth in 1983-87 has been observed to decelerate in all the sectors except agriculture construction and trade Employment growth in manufacturing sector has declined from 3 76 per cent per year in 1977-83 to 2 18 per cent per year in 1983 87 and in services from 4 49 per cent per year to 2 06 per cent per year during the same periods

f) Employment growth in 1983 87 has decelerated from 2 48% per year in 1977-83 to 1 38% per year in 1983-88 in the organised sector and has declined marginally in organised manufacturing sector in 1983-88

g) Public sector has been the major source of employment generation in the organised sector

h) The growth of employment of the educated particularly among the women has been relatively high and has accelerated in 1983-87 as compared to 1977-83

The sectoral distribution of workers given in Table- 2 10 shows that in 1977-78 71 per cent of the workers were engaged in agriculture and allied occupations The proportion had declined to 64 per cent by 1987-88 The corresponding figure revealed by the 1991 census though not strictly comparable with NSS estimates

because of conceptual differences, indicate a marginal decline from 66.5 per cent in 1981 to 64.9 in 1991. Then, a change in the structure of work force by employment status is also witnessed (Table-2.11). The proportion of casual labour increased while that of the self-employment declined from 1977-78 to 1987-88. It is largely a reflection of the occupational shifts from agriculture to non-agriculture and change in pattern of hiring even in agriculture. The share of unorganised sector in non-agricultural employment has increased from 72 per cent in 1977-78 to 77 per cent in 1987-88, at the background of near stagnancy of the share of unorganised sector in overall employment at 90 per cent.

The employment projections in the Eighth Plan have been made using sectoral employment elasticities with respect to output or value added

The non-agricultural sectors registered a rate of growth of employment of more than 3% per annum during 1977-78 to 1987-88. The agriculture sector which engages two third of total work force, registered an average rate of growth of employment of 0 92 per cent per annum. Construction, mining and electricity which together account for about 5 per cent of total employment registered a rate of growth of employment of more than 5 per cent per annum during 1977-78 to 1987-88. Transport sector, which is responsible for 2.8 per cent of total employment generation, experienced an average annual rate of growth of employment of 4 7 per cent in 1977-78 to 1987-88. Manufacturing and services sector account for 11% and 17% of total employment generation respectively Employment in manufacturing and services including trade increased annually by 3 0 per cent and 3 4 per cent respectively during the same period.

A declining trend in elasticity of employment with respect to value added is witnessed in 1983-88. The aggregate employment elasticity with respect to value added estimated as 0 54 during the period 1977-78 to 1983, declined to 0 38 in 1983 to 1987-88. At the disaggregated level, mining and construction are ie two sectors which did not witness decline in elasticity during the above period In agriculture, the elasticity reduced from 0 49 in 1977-83 to 0.36 in 1983-88, implying a decline of 26 per cent. The decline in the elasticity from 1977-83 to 1983- 88 were 62 per cent in manufacturing, 35 per cent in electricity and 57 per cent in transport and other services.

For the purposes of employment projection in the Eighth Plan, the elasticities have been projected to increase mainly through shifts in spatial patterns of growth and labour- intensive composition of output The sectoral employment elasticities are given in Table-2 12.The method of arriving at the sectoral employment elasticities is outlined below

(a) Agriculture

The elasticity in agriculture sector is projected as 0 50 in the Eighth Plan as against 0.36 observed during the period 1983 to 1987-88. The low elasticity observed in 1983-88 is primarily due to steep decline in elasticity in agriculturally advanced states such as, Punjab, Haryana and Uttar Pradesh, where the sources of agricultural growth are now turning to be labour substituting The employment elasticity in agriculture in the remaining regions is observed to be between 0.55 to 1 0 Eighth Plan strategy emphasises faster rate of growth of agriculture in the Eastern region and in dryland areas of peninsular India. It is estimated that if a regionally diversified agricultural output experiences an average annual rate of growth of 4 percent and animal husbandry by 5 per cent, the overall growth of employment in agriculture would exceed 2.5 per cent. Besides, emphasis on crop diversification into non-staple variety particularly in the agriculturally developed regions and faster growth of allied activities such as animal husbandry, fishery, horticulture is expected to add significantly to employment potential in agriculture sector.

(b) Manufacturing

In the manufacturing sector the employment elasticity is projected in the Eighth plan is 0 50 as against 0 26 observed in 1983 88 and 0 68 in 1977 83 This projection is primarily based on the premise that the pattern of manufacturing growth envisaged in the Eighth plan will raise the share of manufacturing output originating from small scale and decentralised sectors The growth in exports has also been from this segment of industry The assumption of larger share of small scale sector in manufacturing growth is based on the trends observed in the recent past More recent data reveal reasonably high employment elasticity in a number of industry groups within the organised sector These include sugar fish canning and preservation tobacco products cotton ginning printing and dyeing woollen textiles leather textiles jute and mesta products glass and glassware The employment elasticity in unorganised and small scale sector is estimated in the range of 0 5 to 0 6 as against 0 15 in the organised sector The growth in value added in small scale sector by 10 per cent per year and in large scale sector by 5% per year would result in overall employment growth in the manufacturing sector by nearly 4 per cent per annum

(c) Construction

Construction as a group and its major sub sectors such as road construction and housing have high employment elasticity An elasticity of 1 0 in construction sector based on the past trend is projected in the Eighth Plan Linking of 31% of the villages with population ranging between 1000 1500 and 10% of those with larger size with motorable roads will alone require construction of 8 lakh km of road length thereby generating greater employment opportunities

(d) Transport

The employment elasticity in transport sector reduced from 0 92 in 1977 83 to 0 35 in 1983 87 The winds of economic liberalisation leading to the relaxation in regulatory measures in transport sector is likely to result in higher growth of small scale transport services whose employment elasticity is higher Keep ng these in view the elasticity in transport sector is projected as 0 60 in the Eighth Plan

(e) Other Services

The services sector witnessed a sharp decline in the employment elasticity from 0 98 in 1977 83 to 0 42 in 1983 87 The measures relating to economic reform and the associated deregulation and removal of bureaucrat c hurdles are expected to result in a significant growth of the services sector as a whole and its small scale segment in particular The objectives in the area of education and health envisaged in the Eighth Plan demanded creation of additional employment potential as a part of infrastructure building activity In tandem a general expansion of economic activities is associated with creation of infrastructure services particularly in the form of employment generation in the tertiary sector whose growth in recent past has been much above the rest of the economy The Services Sector as a major segment of the tertiary sector has witnessed value added growth of about 6% during 1980-81 to 1986 87 as against 4% during the 1970s

The employment intensity of tourism rural transport and repair services is high and these sectors are expected to grow faster with the expansion of agri busi ness in the Eighth Plan Keeping this in view the employment elasticity in the services sector is projected as 0 70 in the Eighth Plan

Estimate of Employment

The required employment generation in order to reduce unemployment to negligible level by the turn of the century has been estimated on the basis of the

backlog of unemployment in the base year and the likely additions to the labour force during the reference period. The backlog of unemployment has been assessed in terms of open unemployment with appropriate adjustments for the severely underemployed who are likely to look for alternative new full time employment opportunities. This is close to the estimate of unemployment measured in terms of "usual" or "weekly" status. The unemployed, according to "weekly status" concept, are without work for the entire period under reference, i.e., they did not have work even for one hour during the week. The extent of unemployment measured in terms of "weekly status" concept enables an assessment of the magnitude of severely underemployed as this method excludes work for half or less than half the time during the reference week.

The latest estimates of employment and unemployment which relates to the year 1987-88 have been adopted to estimate unemployment. The estimate of the magnitude of unemployment at the beginning of the Eighth Plan is obtained as the difference between the estimates of labour force and employment. Total employment at the beginning of the Eighth Plan, i.e., 1992-93 is estimated as 301.7 million on "weekly status" basis The labour force in the age group five - plus is estimated to be 319 million. Thus backlog of open unemployment according to "weekly status" is estimated at 17 million at the beginning of the Eighth Plan. The estimates of employment show that about 2 per cent of those recorded as employed on the basis of "weekly status" had work for half or less than half of the period. These 2 per cent of the employed constituting 6 million in number are treated as "severely underemployed', and are included in the estimates of backlog of unemployment for purpose of manpower planning. Thus the number of persons in the labour force who are likely to search for full time employment opportunities at the beginning of the Eighth Plan is estimated to be around 23 million.

The labour force in five plus age group is projected to increase by about 35 million during the Eighth Plan (1992-97) and by another 36 million during the next five years. Thus, considering the backlog of unemployment of 23 million, the total number of persons requiring employment in the Eighth Plan is estimated as 58 million and 94 million over the ten year period 1992-2002. An aggregate employment growth of about 4 per cent per annum is necessary to achieve the goal of employment for all by the terminal year of the Eighth Plan. Since the feasibility of attaining an employment growth of 4 per cent per year in the Eighth Plan is somewhat remote, an alternative exercise was made whereby the employment objectives in the plan could be realised by lengthening the time horizon The calculations show that, at the background of the output structure envisaged in the Eighth Plan and the subsequent period, aggregate employment growth of around 3 per cent per annum was sufficient to wipe out the backlog of unemployment by the year 2000 AD.

The performance of employment generation in the recent past coupled with the anticipated change in the structure of output in favour of employment intensive investments indicate that an average employment growth of around 2.6 to 2.8 per cent per annum is more likely to be within the realm of feasibility. This growth in employment, if achieved over the next ten years, will be able to create a situation where the economy may attain a near full employment by the end of the Ninth Plan, i e , by 2002 A.D Last but not the least, this calculation and the associated employment scenario will be contingent upon the attainment of a higher average rate of growth of GDP in the Ninth Plan (1997- 2002 A.D.) by 6.28% per year as compared to 5 6% per year adopted in the Eighth Plan (1992-97) and also on the premise that a structural shift in output takes place in favour of the sectors which are relatively more employment-intensive.

The measures outlined in the Eighth Plan are expected to contribute to a faster growth of the economy in the post-plan period and, at the same time will increase the overall employment content of growth. The associated structure of growth of the economy underlined above is able to raise employment elasticity to around 0.5 in the Eighth Plan accompanied by perceptible improvement in labour productivity. As a result, the value added growth rate of 5.6 per cent per year envisaged in the Eighth Plan is likely to result in an employment growth of nearly 2.8 per cent per annum. This

growth in employment is able to generate an average of about 8 to 9 million additional employment opportunities per year. The trend in employment growth in the Eighth Plan is likely to accelerate somewhat in the Ninth Plan due to higher growth of gross domestic product by 6 28% per year with an output structure conducive to employment generation. These are likely to result in the creation of an average of 9 5 million employment opportunities per year in the Ninth Plan. This by and large would be sufficient to reduce unemployment to a negligible level by the end of the Ninth Plan, i e by the year 2002 A D

FINANCIAL RESOURCES SUB-MODEL

The Financial Resources Sub-model estimates the availability of domestic resources consistent with the investment requirement to attain the level of output determined by the input output and investment models The sub-model assesses the level of domestic savings sectorally as well as in terms of its composition using econometric estimation procedure These estimates are consistent with the macro aggregates of the plan The Eighth Five Year Plan envisages total gross investment of the order of Rs 797698 crores over the five year period (1992 97) of the Plan Domestic savings have been estimated at Rs 742835 crores accounting for 93 1 per cent of total investment The remaining Rs 54863 crores are met through foreign savings The net inflow of resources from abroad has been estimated taking into consideration various factors most important of which is the anticipated level of balance of payments deficit on current account The Plan envisages an average rate of investment of 23 2 per cent of GDP The average rate of domestic savings has been estimated at 21 6 per cent of GDP while the rate of foreign savings is placed at 1 6 per cent of GDP This chapter describes the methodology adopted for estimating aggre gate as well as sectoral savings for the Eighth Plan

Domestic Savings

The annual rate of domestic savings in the Indian economy during the 1980s exhibited fluctuations There was a perceptible decline in the rate of gross domestic savings during the Sixth Plan period (1980 85) with the saving rate declining from 22 0 per cent in 1980 81 to 18 2 per cent in 1984 85 This trend was however reversed during the Seventh Plan period (1985 90) when the saving rate increased from 19 7 per cent in 1985 86 to 22 3 per cent in 1989 90 The average rate of gross domestic saving rose from 19 6 per cent during the Sixth Plan period to 20 4 per cent during the Seventh Plan period

The projections of domestic savings during the previous Five Year Plans have generally been based on somewhat optimistic assumptions about the increase in marginal propensity to save to be achieved during the plan periods The rates of domestic savings actually realised during the plan periods however have been at variance with the ones formulated in the Plans For instance in the Sixth Plan assumed that the rate of domestic saving would rise from 21 48 per cent in 1979 80 to 24 88 per cent in 1984 85 whereas the realised savings rate for 1984 85 was 18 2 per cent The Seventh Plan also projected the saving rate to increase from 23 1 per cent in 1984 85 to 24 3 per cent in 1989 90 but the saving rate actually rose from 18 2 per cent in 1984 85 to 22 3 per cent in 1989 90 In the light of this experience the projections of domestic savings for the Eighth Plan have been made rather cautiously The method ology adopted for projecting aggregate domestic savings is explained below

An aggregate savings function has been estimated by regressing Gross Domestic Savings on Gross Domestic Product both being taken at current market prices using annual time series data for the period 1980 81 to 1989 90 While it is true that domestic savings may be influenced by a host of factors other than the income variable GDP has been chosen as the only explanatory variable under the assumption that it has a predominant influence on domestic savings The estimated equation is given below

$$GDS = 5755\ 85 + 0\ 225108\ GDPMP \qquad (1)$$
$$(19\ 978)$$

$$\overline{R}^2 = \quad 0\ 98 \qquad\qquad DW = 1\ 038$$

Where GDS is Gross Domestic Savings and GDPMP is **Gross Domes-tic** Product at market prices.

The marginal propensity to save during the 1980s estimated in the above equation works out 22.5 per cent with respect to GDP at market prices and the estimated coefficient is found to be statistically significant. However, use of the marginal propensity of savings as 22.5 per cent estimated for the period 1980-81 to 1989-90, for projections may involve some degree of overestimation due to the sharp rise in the domestic savings rate from 21.09 per cent in 1988-89 to 22.3 per cent in 1989-90. One has to exercise caution in using the estimated coefficient for the purposes of projections.

Before deciding the magnitude of marginal propensity to save for the Eighth Plan, the elasticity of domestic savings with respect to GDP at market prices through the specification of the saving function in log-linear form for the period 1980-81 to 1989-90 was estimated. The estimated relation is:

$$\text{Log GDS} = -2.084 + 1.038718 \text{ Log GDPMP} \qquad \ldots\ldots(2)$$
$$(18.904)$$

$$\overline{R}^2 = 0.98 \qquad\qquad DW = 0.964$$

The estimated elasticity coefficient from the above   equation is 1.039 and is statistically significant. This coefficient can be considered to be close to unity. It is also worthwhile to note in this context that changes in income influence savings generally with a lag. The elasticity of domestic savings with respect to GDP at market prices is adopted as unity, on the basis of the above reasoning and assuming that changes in GDP in any year will have an impact on domestic saving in the following year. In other words, it is reasonable to assume that the observed elasticity during the 1980s is not very much different from unity. This is also reflected in the near stagnancy of the saving rate during most of this period. In the light of the above analysis, the Eighth Plan postulates that both the marginal propensity and the average propensity to save during the plan period would be of the same order of 21.6, which is the saving rate adopted for 1991-92, the base year of the Eighth Plan. At the background of the annual average rate of growth in GDP of 5.6 per cent set in the Plan, total gross domestic savings over the period 1992-97 have been estimated at Rs. 742835 crores at 1991-92 prices.

Gross domestic savings in the economy is composed of savings in the public and private sectors. The savings in the private sector include the savings of the household sector and the savings of the private corporate and cooperative sectors. The savings in the public sector comprise of budgetary saving of the government and savings of the public sector enterprises. The savings in the different sectors for the Plan period have been separately estimated. The savings performance of the different sectors during the 1980s and the projections for the Eighth Plan are given in Table-3.1.

Sectoral savings in the Plan period have been projected mainly by relating them to disposable income. The framework of inter-sectoral transfers is presented in Annexure-3.1.

Household Savings

The estimates of disposable income and savings of the household sector during the Sixth and Seventh Plan periods along with the projections for the Eighth Plan are given in Table-3.2.   The household sector comprises of individuals, non-government and non-corporate private enterprises engaged in various economic activities as well as non-profit institutions such as charities and trusts. The gross savings of the

household sector are made up of additions to financial assets net of financial liabilities and additions to physical assets including depreciation.

Household savings have been estimated on the basis of their functional relationship with respect to household disposable income. The regression analysis has been carried out using the data for the period 1980-81 to 1989-90 at current prices and in gross terms, i.e., household saving is measured as gross of depreciation provision while household disposable income, used as the explanatory variable, includes the consumption of fixed capital by households. The regression equations have been estimated in the linear and log-linear forms.

$$HS = -11177.371 + 0.246435 \; HDI \qquad ....(3)$$
$$(17.116)$$

$$\overline{R}^2 = 0.97 \qquad\qquad DW = 1.020$$

where, HS is Household Savings and HDI is Household Disposable Income.

$$Log \; HS = -3.9987 + 1.19044 \; (log \; HDI) \; ....(4)$$
$$(15.694)$$

$$\overline{R}^2 = 0.96 \qquad\qquad DW = 1.025$$

The marginal rate of household saving with respect to household disposable income is obtained as 0.24 from equation (3). The estimated coefficient is found to be statistically significant. The elasticity of household saving with respect to household disposable income is estimated as 1.19 in equation (4). The coefficient is statistically significant. However, before making use of these estimated coefficients for the purpose of projections for the Eighth Plan, a careful analysis of the household saving behaviour is considered necessary. Savings-income ratio of household sector witnessed considerable fluctuations during the 1980s. Considering the plan periods as a whole, the average savings-income ratio of households increased from 16.55 per cent during the Sixth Plan (1980-85) to 19.47 per cent in the Seventh Plan period (1985-90). The annual estimates reveal that the savings ratio of households declined from 18.41 per cent in 1980-81 to 15.98 per cent in 1984-85 and the ratio gradually increased to reach the level of 21.81 per cent in 1989-90. In view of this, the use of the estimated marginal coefficient of 0.24 as well as the elasticity coefficient of 1.19, for projections is likely to lead to over estimation of household savings, mainly due to the acceleration it witnessed towards the end of 1980s. Besides, there was no prima-facie reason for continuance of the acceleration into the Eighth Plan period. Moreover, private final consumption expenditure has been postulated to grow at an annual rate of 5.3 per cent during the Eighth Plan as against the average annual increase of 4.3 per cent observed during the period 1980-81 to 1990-91. In view of above, marginal rate of saving in the household sector is projected as 20.3 per cent over the period of the Eighth Plan, while the average rate of saving for the plan period has been placed at 21.0 per cent. On this basis, the total household savings for the Eighth Plan is estimated at Rs. 605170 crores, comprising of gross physical assets of the order of Rs. 288000 crores and net financial assets to the tune of Rs. 317170 crores. The savings of the household sector in the form of physical assets have been independently estimated in the following way.

Savings in Physical Assets

The savings of households in the form of physical assets relate to gross capital formation in terms of productive assets such as machinery and equipment, (both agricultural and non-agricultural), construction of residential and non-residential buildings and structures such as cattle-sheds and worksheds as well as assets created through own account labour in activities such as construction of field bunds, field

channels, deepening of irrigation wells and soil conservation works. The trend growth in gross physical assets in the household sector during 1980-81 to 1990-91 has been estimated at around 18 per cent per annum at current prices and 7.3 per cent at 1980-81 prices. The difference between the two growth rates may be explained by the changes in the index of investment cost.

The share of physical assets in total household savings shows a substantial decline during the 1980s, from 60.6 per cent in 1980-81 to around 50 per cent towards the late 1980s. The decline in the share is accompanied by severe annual fluctuations

The relationship between gross physical assets and gross disposable income of the household sector during the period 1980-81 to 1989-90 has been assessed by regressing the former on household disposable income. The relationship estimated for the above is.

$$PA = -5055.22 + 0.123485 \; HDI \qquad \ldots\ldots\ldots(5)$$
$$(8.639)$$

$$R^2 = 0.89 \qquad DW = 1.427$$

where PA represents gross physical assets and HDI represents gross household disposable income, both being at current prices.

Although the coefficient of 0.123 estimated from the above equation is found to be statistically significant, it has been considered realistic to assume a marginal coefficient of 0.10 for the purpose of projections of physical assets for the Eighth Plan. There has been a decline in the share of physical assets in total household savings during the 1980s. Total gross savings in the form of physical assets in the household sector has thus been estimated at Rs.288000 crores for the Eighth Plan. This accounts for 47.6 per cent of total household savings of Rs. 605170 crores during the Plan. The savings in financial assets constitute the remaining 52.4 per cent of the total savings, amounting to Rs. 317170 crores.

Savings in Financial Assets

The financial assets of the household sector consist of currency, deposits with commercial banks and cooperative institutions as well as non-banking companies, investment in shares and debentures including units of Unit Trust of India and mutual funds, life insurance funds, contributions to provident funds and pension funds and net claims on government. Savings of the household sector in the above mentioned categories of financial assets represent net addition, i.e., net of financial liabilities of the hosusehold sector. Household savings in different types of financial assets, which taken together amount to Rs. 317170 crores for the plan period, have been estimated separately for each category of financial asset, as shown in Table-3.3. The methodology adopted for estimating saving in financial asset is discussed below.

The outstanding amount of currency with the public, as on the 31st March, increased from Rs. 13426 crores in 1981 to Rs. 53087 crores in 1991 registering an annual growth of 14.7 per cent. On the other hand, the trend growth rate of GDP at current market prices for the period 1980-81 to 1990-91 is estimated at 14.10 per cent. The elasticity of currency with respect to GDP at market prices works out to 1.04. The elasticity of currency held by household alone with respect to GDP at market prices turns out to be marginally lower at 1.01 as compared to the elasticity of 1.04 estimated for currency held with the public. Considering the recent instruments introduced in the capital market to attract particularly the small investors in the household sector, it may be reasonable to project a marginal decline in the elasticity for currency held with households. On this basis, elasticity for currency held with the household is projected

as 0.9 during the Eighth Plan. As the basis of the growth of 5.6 per cent per annum in GDP in the plan, the growth in currency is estimated at 5.0 per cent. The savings of households in the form of currency are thus estimated at Rs. 41775 crores, which has been worked out as the difference in the currency held by the households between the base and terminal years of the plan.

Aggregate deposits with the scheduled commercial banks increased from Rs. 38348 crores in 1981 to Rs. 204774 crores in 1991, registering an annual growth of 18.2 per cent. The bank deposits held by households, however, increased at a marginally higher rate of 18.6 per cent during the same period. The elasticity of demand for aggregate bank deposits with respect to GDP at market prices for the period 1981-89 is estimated at 1.29, while the same for bank deposits held by households is estimated at 1.32. The structural changes initiated to reform the financial sector is witnessing a preference pattern which is different from the past. This is likely to change the structure of savings, ultimately leading to competition between various financial instruments. For example, there is a competition between mutual funds and bank deposits. In view of this, the elasticity of household demand for bank deposits has been reduced marginally to 1.3 in the plan period. The demand for bank deposits in the household sector is postulated to grow at 7.3 per cent during the plan period. Savings in the form of net addition to bank deposits have been calculated as the difference in the bank deposits held by households between the base and terminal years. Total household saving in the form of commercial bank deposits is thus estimated at Rs. 50900 crores for the Eighth Plan.

Household savings in the form of deposits with cooperative banks and societies have been around 10 per cent of household deposits with commercial banks. Using this ratio, the household savings by way of deposits with cooperatives during the Eighth Plan have been estimated at Rs. 5090 crores.

The deposits of the household sector with non-banking companies include deposits with financial as well as nonfinancial companies in both private and public sectors. Such deposits amount to about 15 per cent of household deposits with commercial banks during the Seventh Plan period. This ratio has witnessed marginal decline recently. However, the non-banking companies have started attracting household deposits through innovative schemes such as the issue of post-dated monthly interest cheques for the whole year in advance, providing maximum interest rate admissible for term deposits for even shorter maturity periods, cumulative interest deposits, etc. In view of these developments deposits with non-banking companies have been assumed at 15 per cent of household deposits with commercial banks during the Eighth Plan. The deposits of households with non-banking companies following this have been estimated at 7600 crores.

Household savings in the form of investment in shares and debentures include investment in private corporate and cooperative sectors as well as investment in bonds of public enterprises and in schemes of mutual funds. The household investment in shares and debentures registered a rapid growth of around 27 per cent per annum during the 1980s. This reflected in the buoyancy witnessed in the capital market. The elasticity of such investment with respect to household disposable income works out to about 1.9 for the 1980s. On this basis, the growth in household sector's investment in shares and debentures is estimated to rise by 10 per cent per annum for the Eighth Plan. The total household investment in these financial instruments is thus estimated at Rs. 82990 crores.

Household savings in the form of insurance funds cover life insurance, postal insurance and Central and State Government employees group insurance funds. The savings of households in all these types insurance funds increased at 19.4 per cent per annum during the 1980s. The elasticity of insurance funds with respect to household disposable income works out to about 1.4. Using this elasticity, household savings in insurance funds are estimated to grow at annual rate of 7.4 per cent during

the Eighth Plan. Total household savings in insurance funds are placed at Rs. 32865 crores for the Plan period.

Household savings in the provident funds cover Central and State Government provident funds, non-government provident funds, public provident funds and pension funds. Household savings in provident funds registered an annual growth of 18.1 per cent during the 1980s. The elasticity of savings in provident funds with respect to household disposable income is estimated at 1.3 for the 1980s. On the basis of this elasticity, the provident funds can increase at an annual rate of around 7 per cent during the Eighth Plan. However, in view of the tax incentives and the fairly high rates of interest given for such funds, a higher growth of 8 per cent per annum has been assumed for such savings during the Eighth Plan. Household savings in provident funds are thus estimated at Rs. 70580 crores for the Eighth Plan.

Household claims on government include small savings, government securities and various types of bonds floated by the government from time to time. Such claims registered an annual growth of nearly 27.5 per cent during the 1980s. The high growth rate could be attributed mainly to special tax incentives given under various small savings schemes. The elasticity of savings in these instruments with respect to household disposable income is high at around 1.86 for the 1980s. Towards the end of the decade this elasticity increases to 2.0. Using this elasticity, net claims of household on government are expected to increase at around 11 per cent per annum during the Eighth Plan. Such claims have been estimated at Rs. 25370 crores for the Eighth Plan.

The total financial savings of households covering all kinds of financial instruments are thus estimated at Rs. 317170 crores for the Eighth Plan, as shown in Table-3.3. There would be substantial changes in the structure of financial assets held by the household during the plan resulting from changes in household preferences for different types of financial instruments. The share of deposits held by households with commercial banks and non-banking companies in their total financial saving is expected to decline from 26.6 per cent in the period 1985-90 to 20 per cent during the Eighth Plan period. On the other hand, the share of household savings in the form of shares, debentures and units of Unit Trust of India and other mutual funds is expected to increase from 9.4 per cent in 1985-90 to 26.2 per cent during 1992-97. However, household savings in the form of insurance funds and provident funds would follow the trend growth rates observed in the past, partly due to the compulsory nature of these savings instruments and partly due to the tax benefits provided for their forms of savings.

Savings in the public sector

The decade of the 1980s witnessed a sharp decline in the share of public sector savings in aggregate domestic savings. Gross savings of the public sector as a proportion of GDP at market prices declined from an average of 3.64 per cent during 1980-85 to 2.22 per cent in 1985-90. This decline in the ratio of public sector savings has been caused mainly by the poor savings performance of the government sector. The savings of government as a proportion of GDP at market prices deteriorated sharply during the 1980s, from an average of 0.94 per cent in 1980-85 to (-) 1.54 per cent in 1985-90. However, the extent of erosion in public sector savings caused by the poor savings performance of the government was minimised to a certain extent by the better savings performance of public enterprises. The average ratio of gross savings of public enterprises to GDP at market prices increased from 2.70 per cent in 1980-85 to 3.76 per cent in 1985-90.

Government Savings

The savings of the Government for the Eighth Plan have been projected on the basis of estimates of government disposable income. Table-3.4 shows that total receipts of Government as a ratio of GDP at market prices increased from an average

of 16 61 per cent during 1980-85 to 18.77 per cent in 1985-90. It is projected as 20.86 per cent during 1992-97. Tax receipts ratio which increased by 1.64 percentage points between 1980-85 and 1985-90 is expected to rise by 1.69 percentage points in 1992-97. The collection of direct taxes which declined from an average of 2.65 per cent of GDP to 2.52 per cent between 1980-85 and 1985-90, is projected to increase to 3.00 per cent of GDP in 1992-97. The rise in the direct tax ratio is envisaged mainly through broadening of the tax base and thereby widening the tax net. On the other hand, the ratio of indirect taxes to GDP which increased by 1.76 percentage points from 12.89 in 1980-85 to 14.65 in 1985-90 is postulated to rise by 1.21 percentage points to reach the level of 15.86 per cent during 1992-97. The relative rise in the indirect tax ratio envisaged during the Eighth Plan is attributed to the reforms in the structure of excise and customs duties. The ratio of receipts from entreprenurship and property taxes to GDP rose by 0 40 percentage point, from 0.79 per cent in 1980-85 to 1.19 per cent in 1985-90. This ratio is projected to increase only by 0.32 percentage points to reach 1.51 per cent in 1992-97. The relatively smaller increase in this ratio during the Eighth Plan may be attributed to two factors. One is that the public enterpnses would be accorded greater autonomy to retain their profits in order to meet their own investment needs. Secondly, the public enterprises would have to share their profits with the new equity holders following the disinvestment of equities held by the government.

The total transfers from the government to the rest of the economy as a proportion of GDP rose by 2.96 percentage points from 6.61 per cent in 1980-85 to 9.57 per cent in 1985-90. This ratio is, however, expected to increase by only 1.61 percentage points during the Eighth Plan to reach an average of 11.18 per cent during 1992-97. This is sought to be achieved through a reduction in the ratio of subsidies to GDP from, 3.57 per cent in 1985-90 to 3.12 during 1992-97. Furthermore, the growth in current transfers is also to be contained to modest levels. However, the ratio of interest on public debt to GDP is expected to increase sharply from 2.96 per cent in 1985-90 to 4.79 per cent in 1992-97. This is on account of the past commitments on debt accumulated during the 1980s and hence not amenable to control within a short period. Due to the changes in the ratios of receipts and transfers of the government, the ratio of government disposable income to GDP which showed a consequent decline from 10.0 per cent in 1980-85 to 9.2 per cent in 1985-90. This is projected to rise marginally to nearly 9 7 per cent during 1992-97.

In order to improve the savings performance of the Government, the Eighth Plan envisages substantial containment in the growth of government final consumption expenditure. The ratio of consumption expenditure to GDP which increased by 1.74 percentage points between 1980-85 and 1985-90 is now postulated to rise by only 0.22 percentage points between 1985-90 and 1992-97. The deterioration in government savings performance witnessed during the 1980s is thus sought to be reversed during the Eighth Plan by bringing down the negative savings ratio from 1 54 in 1985-90 to 1 1 in 1992-97.

Savings of Public Enterprises

Gross savings of public enterprises, including railways and communications, as a proportion of GDP increased from an average of 2.7 per cent during 1980-85 to 3.76 per cent and in 1985-90. This ratio is, however, expected to be in order of 3.1 per cent during the Plan period 1992-97. The decline in the savings ratio of public enterprises and is postulated through the account various Gross savings of public enterprises and may contribution of large profits in a few and communications. Furthermore, the other sectors and from rise in administered prices and other and the sectors were either losses or were not generating enough operating surpluses for financing their capital expenditure for modernisation and expansion process of restructuring of Public Enterprises is expected to be set into motion in the current trend of exposing the public enterprises both in the product and in the capital market. On account of these, the profits of public enterprises are likely to be some extent

during the initial phase of restructuring as the costs of such restructuring have to be met mostly out of their own resources. However, profits of public enterprises are likely to rise once the process of restructuring is complete.

Savings of Private Corporate Sector

Gross profits of the private corporate sector as a proportion of GDP increased from 1.64 per cent during 1980-85 to 2.08 per cent in 1985-90. This ratio is, however, postulated to decline to an average of 2.00 per cent during the Eighth Plan, 1992-97. The decline in this ratio is prompted by economic reforms. The private corporate sector has, hitherto, been making large profits in an environment of sheltered domestic market. With the lowering of tariffs and large scale removal of quantitative restriction, the private corporate sector has to compete with imports in terms of both price and quality. This challenge is certain to initiate a process of restructuring of the private corporate sector. This include mergers, foreign collaborations with companies, technological upgradations, modernisation diversification, etc. During this phase, the expansion of private corporate sector would rest on investments through domestic and foreign borrowings or through direct foreign investment. The impact of the investments on production and profits will be reflected with a time lag. Due to these considerations, the contribution of profits of the private corporate sector has been assumed at 2 per cent of GDP during the Eighth Plan.

CHAPTER-4

AGRICULTURAL SUB-MODEL

Agricultural sub-model has a two way use in the determination of agricultural output target in the Plan. First, the impact of application of certain critical inputs such as land and other infrastructure both in terms of quality and quantity on agricultural production and productivity in the long and medium term cannot be appropriately captured in the input-output model. Then, in the context of regional development, locational aspects of agricultural growth in terms of crops and input-intensity are also not possible to be quantified under the input-output frame. Besides several features of the agricultural plan such as development of rainfed areas and agricultural planning in terms of homogenous agro-climatic regions are also captured in the agricultural sub-model. The agricultural sub-model assesses the feasibility of output targets on the basis of detailed requirements and use of inputs at the background of above factors.

The sub-model determines crop output at detailed regional level treating area allocation under different crops and between different seed varieties as exogenous. The supply is determined at regional level using land, water, seed, fertiliser as explanatory variables. The model specification is not uniform for all the regions. The supply of foodgrains is estimated from this model. The demand for foodgrains is estimated from consumption sub-model as well as input-output model. The feasibility of demand for foodgrains is tested with its supply estimated from the regional models. The determinants of supply and parameters affecting supply have been estimated separately for each major states.

The agricultural sub-model assesses the production possibilities of agricultural crops for the Eighth Plan (1992-97) and also for the perspective period (1997-2007). The framework of the model consists of a set of econometric relationships among critical variables in the agricultural sector such as net sown area, gross cropped area, expansion in irrigation facilities, irrigated area under foodgrains, fertiliser consumption, rainfall index and yield levels, using time-series data. The production levels of foodgrain crops for the terminal (1996-97) and post-terminal (2006-07) years of the plan have been worked out from econometric modelling and also taking into account other relevant factors such as production performance in the recent past and the gaps between supply and demand of major crops. The estimated parameters are chosen after considering alternative specifications in terms of explanatory variables and functional forms based on single equation least square method.

The agricultural sub-model takes care of the supply side of the problem. The demand side is taken care of partly in the input-output model and partly in the consumption sub-model. The private consumption demand is obtained from a two stage nested behaviouristic consumption model where demand for foodgrains are estimated separately for rural and urban areas and within each area for people living below and above the poverty line using respective expenditure-elasticities. The inter-industry demand for agricultural commodities and the quantum of foodgrain stocks are estimated in the input-output model. The supply of foodgrains is estimated at a regional level by relating production with land and other inputs using econometric estimation procedure. The demand for agricultural commodities arising from private consumption, inter-industry use and stocks are matched with the supply which is worked out in the agricultural sub-model.

Net Sown Area, Gross Irrigated Area and Fertiliser Consumption

There is a severe land resource constraint in the economy, which is evident from the fact that net sown area has been hovering around 140 million hectares during the past two decades. There is also an increasing demand for land for non-agricultural usage such as industrial and commercial activities and housing in the

countryside. Keeping these in view, it has been assumed that Net Sown Area (NSA) would remain constant at 141 million hectares from the terminal year of the plan (1996-97) through the perspective period. At the background of land constraint acceleration in agricultural growth can take place only through a faster growth in cropping intensity. This depends much on the expansion and efficient use of irrigation facilities. The gross irrigated area from all sources (in terms of utilisation) is expected to increase from 75.7 million hectares in 1991-92 to 89.3 million hectares in 1996-97 and to 114 million hectares by 2006-07. The total supply of fertilisers available for use in the agricultural sector in the year 1996-97 has been estimated at 18.3 million tonnes, of which 70 per cent viz., 12.8 million tonnes is expected to be consumed by foodgrain crops.

Gross Cropped Area and Cropping Intensity

In the present framework, gross cropped area under all crops (GCA) has been estimated by relating it to net sown area (NSA) and gross irrigated area (GIA) using econometric model. The details of the model results are given in Annexure-4.1. Based on the assumption of expansion in net sown area and irrigation, GCA is expected to increase to 190.6 million hectares in 1996-97 and 203.4 million hectares by 2006-07 (Table-4.1). The above implies that the cropping intensity defined as the ratio of GCA to NSA would rise from 1.30 in 1991-92 to 1.35 in 1996-97 and to 1.44 in 2006-07. The ratio of gross irrigated area to gross cropped area would also increase from 41.5 per cent to 46.9 per cent during the Eighth Plan period and further rise to a level of around 56 per cent by 2006-07.

Gross Cropped Area and Irrigated Area under Foodgrains

Gross cropped area under foodgrains (GCA fg) has been estimated by relating it with gross cropped area under all crops. Similarly, gross irrigated area under foodgrains (GIA fg) has been estimated by relating it with the gross irrigated area under all crops. The details of the econometric models used to arrive at the estimates of gross cropped area, gross irrigated area and foodgrains are given in Annexure-4.1.

On the basis of the estimated model, gross irrigated area under food-grains has been projected to increase from 53.8 million hectares in 1991-92 to 62.3 million hectares in 1996-97 and 77.7 million hectares in 2006-07. Gross cropped area under foodgrains is expected to increase from 127 million hectares in 1991-92 to 130 million hectares in 1996-97 and reach a level of 135 million hectares by 2006-07 (Table-4.2). The ratio of irrigated area to cropped area under foodgrains is thus expected to rise from around 42.4 per cent in 1991-92 to 47.9 per cent in 1996-97 and to 57.6 per cent in 2006-07.

Foodgrain Output

There has been a substantial increase in foodgrain production in the country since early 1970s mainly due to growth in productivity. The average yield of foodgrains increased from about 850 kg/ha in the early seventies to about 1350 kg/ha in the late eighties. This increase in productivity has been made possible mainly by three factors, viz., expansion of irrigated area, rise in fertiliser consumption and expansion of area under high-yielding varieties (HYV) of cereal crops. The task of building an econometric model incorporating all these variables has been found to be rather difficult particularly due to the existence of high degree of multicollinearity among these variables. It has also been difficult to evaluate precisely the relative contribution of these factors to overall productivity growth. In the present framework, the foodgrain production at all-India level has been estimated by relating it to increase in area under foodgrains and yield. Simultaneously, production of foodgrains has been estimated separately for 17 major states which account for about 98 per cent of the total foodgrain production in the country on the basis of a regional state specific foodgrain model developed for this purpose.

The yield of foodgrains at all-India level has been related to per hectare fertiliser consumption under foodgrains (FCPUCfg) and the rainfall index (RIND), on the premise that the variable per hectare fertiliser consumption would capture the effect of expansion of both area and fertiliser consumption. The estimate of fertiliser consumption for foodgrain crops is placed at 70 per cent of the fertiliser consumption for all crops. Rainfall index (RIND) has been considered as a separate explanatory variable since more than 50 per cent of the area under foodgrains is still dependent on rainfall. The fluctuations in rainfall is likely to affect the gross cropped area and availability of water for irrigation. Assuming normal weather conditions, foodgrain production has been projected to increase from 172.5 million tonnes in 1991-92 to 210 million tonnes in 1996-97 and 285 million tonnes by 2006-07 (Table-4.2). The results of econometric exercises show that two variables, viz., fertiliser consumption per hectare for foodgrain crops and the rainfall index are able to explain about 95 per cent of the changes in productivity measured in terms of yield.

The statewise foodgrain production for 1996-97 has been projected using estimated parameters of the econometric model and also taking into account the production performance, fertiliser consumption and area under cultivation in the recent past. The total foodgrain production in the terminal year of the plan has been estimated from an assessment of the regional production plans. The regional production plan, in turn, are based on detailed econometric exercises involving major inputs. The model structure for the region has finally been set on the basis of the relative importance of the variables in influencing production and the overall predictive power of the model. The model results are given in Annexure-4.3.

The results show that gross cropped area under foodgrains (GCA fg) and fertiliser consumption are the major variables that influence foodgrain production in the region. The fertilisers consumption and GCA(fg) at regional level for 1996-97 have been projected on the basis of their actual growth performance during 1980's, and the anticipated changes in the Eighth Plan. The foodgrain production for Assam, Himachal Pradesh, Jammu & Kashmir and Karnataka are estimated on the basis of the past performance and recent trend, as the econometric estimation procedure was not able to produce statistically significant results. The projected foodgrain production, fertiliser consumption and area under foodgrains at regional level are given in Table-4.4. In case of foodgrains, the contribution of area and yield in the total production have also been estimated at regional level (Table-4.5). These statewise foodgrain production estimates adds upto 210 M.T. which is the target set for the Eighth Plan.

Gross Cropped Area, Irrigated Area and Output of Major Food Crops

Gross cropped area under rice and pulses have been estimated as a function of gross cropped area under foodgrains. The gross cropped area under wheat and other cereals have been estimated on the basis of the trend in the recent past. While the output of wheat, pulses and other cereal crops have been estimated by relating them with the gross cropped area and fertiliser consumption under these crops, the output of rice has been estimated by considering rainfall index as an additional explanatory variable along with gross cropped area and fertiliser consumption.

At the all-India level, nearly 80 per cent of the area under wheat is irrigated, while it exceeds 90 per cent in the major wheat growing states such as Haryana, Punjab and Uttar Pradesh. As the irrigation potential in major wheat growing states have already reached an asymptote, it is, therefore, expected that rice would account for the most of the expansion of irrigated area under foodgrains in future. Even then, the percentage of irrigated area under rice might only reach a level of around 60 per cent by 1996-97 and the remaining 40 per cent of the cropped area under rice would continue to be dependent on monsoons. The percentage of irrigated area under coarse cereals and pulses is not expected to undergo perceptible change during the Eighth Plan. The estimated production for the crops are given in Annexure-4.2.

Targets of Principal Crops
Rice

The production of rice is postulated to increase at an annual rate of 4 per cent from an estimated level of 72.5 million tonnes in 1991-92 to 88.0 million tonnes in 1996-97, mainly due to growth in productivity (Table-4.3). While the area under rice is likely to increase only by about 0.5 per cent per annum, the average yield of rice is expected to increase from 1706 kg/ha. to 2023 kg/ha. during 1992-97, showing a rate of growth of 3.5 per cent per annum. The growth in the yield of rice is expected to originate primarily from expansion in irrigation and area under HYV, supplemented by growth in fertiliser consumption. These projections are broadly consistent with the trends observed during the 1980s. Between the period 1981-84 and 1989-92, rice production registered a growth of 4.2 per cent per annum of which growth in productivity accounted for 3.5 per cent and growth in area accounted for 0.7 per cent (Annexure-4.4).

Wheat

The area under wheat fluctuated around 23 to 24 million hectares during the Seventh Plan period and is expected to increase marginally to 24.25 million hectares by 1996-97 (Table- 4 3). The production of wheat is postulated to increase from 56 million tonnes at the beginning of the Eighth Plan to 66 million tonnes by the end of Eighth Plan showing a growth of 3 3 per cent per annum. A large part of the growth in production would accrue from increase in yield from 2383 to 2722 kg. per hectare representing an annual rate of growth of 2 7 per cent. These projections are broadly consistent with the growth performance of wheat observed during the 1980s, as can be seen from Annexure-4 5.

Coarse Cereals :

The production of coarse cereals between 1981-84 and 1989-92 increased at an annual rate of 0 28 per cent (Annexure-4 6). The growth in production was exclusively due to growth in yield by 2.1 per cent per annum, which more than compensated the decline in area by 1 7 per cent per annum during the same period. Furthermore, it is observed that there has been some acceleration in the output growth of coarse cereals during the Seventh Plan period when production increased at an annual rate of 2 2 per cent due to faster growth in yields at about 3.1 per cent per annum. However, the low level of yield in 1991-92, the base year for the Eighth Plan, at around 800 kg/ha and coupled with the projected yield of 1996-97 at 1033 kg/ha resulted in a sharp increase in productivity growth of the order of 5 2 per cent per annum in the Eighth Plan It may be mentioned that the average yields of coarse cereals were above 900 kg/ha both in 1989-90 and 1990-91, while it declined to around 800kg/ha in 1991-92 due to adverse weather conditions. Hence, if one makes an adjustment for the base year yield assuming normal weather conditions, the growth in productivity from the long term trend values would be around 3 per cent per annum for the Eighth Plan. On the basis of the projected yield level of 1033 kg/ha for 1996-97, the production of coarse cereals is expected to reach a level of 39 million tonnes by 1996-97 (Table-4 3)

Pulses:

The production of pulses has not shown any significant increase during the eighties. Between the periods 1981-84 and 1989-92, production increased at an annual average rate of only one per cent which was mainly due to growth in productivity of the order of 0 9 per cent per annum (Annexure-4 7) However, during the Seventh Plan, production of pulses increased by about 1 5 per cent per annum, mainly as a result of the initiatives taken under the National Pulses Development Programme. Pulses being a major source of protein for the poorer sections of the population, it is essential to achieve a much faster rate of growth in production through greater emphasis on the National Pulses Development Programme. It is postulated that the area under pulses would increase by one million hectares, while productivity is expected to increase by about 3.1 per cent per annum during the Eighth Plan. As a result,

production of pulses is likely to reach a level of 17 million tonnes by 1996-97 from the estimated production of 14 million tonnes in 1991 92 (Table-4 3)

Foodgrains

The foodgrain production increased at an annual average rate of 2 76 per cent between 1981-84 to 1989-92 (Annexure-4 8) The respective contribution of area and yield in growth of foodgrain production is given in Annexure-4 9 Foodgrain production is expected to increase from 172 5 to about 210 million tonnes during the Eighth Plan period an increase of about 37 5 million tonnes as compared to the increase of 25 million tonnes in the Seventh Plan period The annual average rate of growth in foodgrain production in the Eighth Plan is thus expected to be of the order of about 4 per cent as compared to 3 3 per cent realised during the Seventh Plan period Much of the growth in foodgrain production during the Eighth Plan is likely to originate from growth in productivity of the order of 3 5 per cent per annum (Table-4 3) Taking into account the projected increase in population from 844 million in 1991 to 941 million by 1996 97 and also the rise in demand for food associated with the growth in income foodgrain demand is expected to reach a level of 208 million tonnes by 1996-97 Thus the postulated growth in production of foodgrains will help in improving the per capita consumption of foodgrains from 182 kg per annum in 1991-92 to 193 6 kg per annum by 1996 97 This would help in achieving the goal of self sufficiency in food during the Eighth Plan period

N B. Production in '000 tonnes

CHAPTER- 5

THE INDUSTRY SUB-MODEL

The structure of the industry sub-model is based on the approach of material balances which has been an important feature in the planning process since the Third Five Year Plan. The material balance studies serve the purpose of supplementing and cross-checking the results obtained from the multisectoral Input- Output (I-O) model

There are certain basic differences between input-output analysis and the material balance approach. The static framework of the I-O model provides economywise sectoral projections of output for the terminal year of the Plan which are consistent with the overall rate of economic growth postulated in the Plan. On the other hand, the material balance studies help in estimating output for selected commodities and services on the basis of independent demand and supply projections. The technical coefficients in the I-O model are expressed in value terms at constant prices, while the material balance studies use input coefficients or norms in physical units. The projections obtained through the I-O model relate to sectors which in many cases comprise more than one commodity or product (e g., all types of petroleum products) while the material balance studies generally relate to single commodities or services. The I-O model provides projections of sectoral output based on interindustry demand and final demand. There are independent projections of supply in the I-O model. The material balance studies provide independent estimates of demand and supply for selected commodities and services

In general, the demand projections in the material balance approach are based on the end-use method covering both interindustry use as well as final use. The demand projections are obtained by applying the input norms to the exogenously estimated terminal year output of consuming or user industries. The supply projections in the material balance studies are made on the basis of information relating to existing capacities, rates of capacity utilisation, projects in pipeline and creation of additional capacities during the plan period Given the uncertainties in the completion of projects at different stages of construction, the supply projections in the material balance studies can be considered as feasible output levels during the plan period. Despite some limitations, the material balance approach serves a useful purpose of cross-checking the results obtained through the I-O model.

The changes in process of production take place at the level of commodity. Such changes can be captured through commodity-specific studies of demand and supply. A sector of I-O table being an aggregate of many commodities, it is difficult to account for technological changes at the level of sectors Material balance approach is therefore found to be a useful supplement to the I-O approach.

The methodology adopted for preparing material balances for the Eighth Plan remains broadly the same as explained in the Technical Notes of the Sixth and Seventh Five Year Plans However, the physical input norms for various types of end-uses of a fairly large number of commodities prepared earlier have been revised and updated using more recent data from the different sources The updated input norms take into account changes in product/process technology as well as comodity substitution in interindustry use and also changes in final demand due either to price or other factors. Further, the input norms for the terminal year of the Plan have been modified, wherever necessary, in order to reflect technological changes or commodity substitution that are likely to take place during the plan period.

The list of the commodities for which material balance studies have been carried out for the Eighth Plan is given in Table 5.1. A brief description of the methodologies adopted for selected commodities is given below.

COAL

The major sectors which consume coal are power, steel and metallurgical industries, manufacturing industries including small scale industries, and railways. The household sector also uses coal for domestic purpose. Power, steel, cement and fertiliser plants which account for about 75 per cent of the total coal consumption in the country are considered as distinct end-users in the material balance for coal.(Table 5.2) Using the recent statistics for these sectors, it has been possible to estimate their coal input coefficients.

While the efficiency of use of heat energy in thermal plants has improved due to improvement of technology in the new plants and in plants with higher capacity such as super thermal power stations, the coal consumption norm has not shown improvement due to deterioration in the quality of coal supplied to the thermal plants. The demand for coal in the thermal power sector has been estimated after making necessary adjustments in the coal consumption norm for quality parameters and also for improvement in the operating efficiency of the plants. Besides utilities, there is now a substantial power generation by captive power plants in the industrial sector. The projection of coal for power generation includes both the utilities and the non- utilities.

Steel plants are the major consumers of coking coal, while some coking coal is also supplied to merchant coke ovens for producing hard coke used in the foundries and forges. Requirement of raw coking coal by steel plants depend primarily on the production programme of hot metal The ratio of coal to hot metal in turn, depends to a great extent on the quality of coking coal and other raw materials as well as other factors such as the process technology and the scale of operation. The technology adopted at present does not permit exclusive use of coking coal domestically available due to its high level of ash content. The indigenous wahsed coal has, therefore, to be blended with imported coal before charging to coke ovens. A programme for modernisation of the various steel plants has been initiated with a view to adopt more energy efficient technology and this is expected to bring down the coal to hot metal ratio. Besides setting up new washeries, the existing ones are also being modernised which would improve the quality of coal These measures are expected to bring down the consumption of coking coal per unit of steel output

Sponge iron is used mainly in mini-steel plants to produce steel by electric arc furnace process As a policy measure, setting up of sponge iron plants is being encouraged in order to reduce the dependence of mini steel plants on scrap. The existing sponge iron plants use non coking coal as a reducing agent Demand of coal for this sub sector is estimated from the capacity of coal based sponge iron plants that is likely to come up in the Eighth Plan

Coal is used by various industries such as fertilisers, cement, paper, textiles and rayon, glass and ceramics, refractories, brick kilns etc. Of these, cement and fertilizer industries are the major consumers of coal. In respect of the cement industry, dry process technology is more energy efficient and all the new plants would adopt this technology. This factor has been taken into account while estimating the specific coal consumption norm and projection of demand for coal in the cement industry. In the case of fertiliser industry, more emphasis is being laid on gas-based plants and hence the demand for coal is not expected to increase The requirement of coal for the remaining industries in the manufacturing sector such as glass and ceramics, brick kilns, etc , has been projected on the basis of past trends due to lack of reliable data about their coal consumption and corresponding levels of production.

The requirement of coal by railways has been steadily declining on account of increased dieselisation and electrification of railway tracks. This trend is expected to continue during the period of the Eighth Plan as well.

67

The offtake of soft coke for domestic use is gradually declining due to high delivery cost and the consumer preference for cleaner cooking fuels like kerosene and LPG. In order to reduce the imports of petroleum products like kerosene and also with a view to reduce deforestation, it is necessary to encourage the use of soft coke as a substitute cooking fuel. Central Mine Planning and Design Institute Limited (CMPDIL) has developed a mechanised manufacturing process which provides soft coke as a smokeless fuel and also enables recovery of by-product. If this process proves to be successful the demand for soft coke could pick up in the near future.

Crude Petroleum

Refinery throughput in 1991-92 has been estimated at 51 42 million tonnes. With the expansion of the existing refineries and the commencement of production in the two new refineries viz Mangalore and Cauvery refineries refinery throughput is expected to reach 63 3 million tonnes by 1996-97 as against the projected domestic production of 50 million tonnes of crude petroleum.

Petroleum Products

Petroleum products which are put together as a single sector of I-O Model comprise variety of products and the end use of each product differs from the other. Consumption of petroleum products is therefore studied by type of product and by the end use (Table 5 3).

The petroleum products are generally classified into three broad categories based on their physical properties and their applications. The category of light distillates comprises liquid petroleum gas (LPG) naphtha motor gasoline (Mogas) and other light distillates like special boiling point spirit (SBP) and haxane. The category of middle distillates consists of kerosene (SKO) high speed diesel (HSD) aviation turbine fuel (ATF) low speed diesel oil (LDO) and other minor fractions like jute batching oil (JBO) mineral terpentine oil (MTO) etc. The category of heavy distillates include fuel oil low sulphur hot stock (LSHS) heavy hot stock (HHS) lubes and greases bitumen petroleum coke and other minor fractions.

The demand for petroleum products for road transport sector has been projected on the basis of the past relationship observed between the population of registered motor vehicles and the intensity of their utilisation. The requirement of ATF in the air transport sector has been projected on the basis of past trend. Demand for petroleum products in the rail transport sector has been projected on the basis of originating traffic.

The demand for naphtha LSHS and other petroleum products used in fertiliser and petrochemical industries have been projected on the basis of plantwise requirement and also taking into account the use of natural gas in some of the existing units and the new plants that are likely to be set up during the Plan period. Natural gas is expected to serve as a substitute for petroleum products in power fertilisers petrochemicals and sponge iron industries. Efforts are also being made to use compressed natural gas (CNG) as a substitute for HSD in road transport.

The factors influencing demand for kerosene are substitution of kerosene by electricity for lighting of households and substitution of kerosene by LPG as a cooking fuel. Increase in use of electricity as a primary source of lighting has been faster in rural areas - where three-fourths of population is located, than in urban areas (Table 5 4). The shift from kerosene to LPG as a cooking fuel has been sharper in urban areas. As a combined effect of these two factors, the drop in growth rate of kerosene consumption has been much sharper than the decline in growth rate of population (Table 5 5).

The relationship between growth of kerosene consumption by households and growth of population observed in the Seventh Plan is expected to continue in the Eighth Plan Projected demand of 12100 thousand tonnes of kerosene in 1996-97 includes 529 thousand tonnes required for industrial consumption

The consumption of LPG for domestic use has increased from 953 thousand tonnes in 1984 85 to 2268 thousand tonnes in 1989 90 Keeping in view the availability of LPG from refineries and natural gas fractionation plants (C3/C4 fraction) it is envisaged to provide 18 lakh new connections per year during the Eighth Plan period Assuming an average consumption of 129 kg per year per household the demand of LPG for domestic use works out to 3634 thousand tonnes in 1996-97 The demand for LPG in the industrial sector has been projected at 403 thousand tonnes based on past trend and also taking into account the increasing use of natural gas in the industries

There has been a gradual reduction in the consumption of FO/LSHS in the power utilities during the last few years partly due to the reduction in specific consumption of FO/LSHS and partly due to the increase in the share of gas based power generation The specific consumption norm has declined from 14 9 ml/kwh in 1985 86 to 10 1 ml/kwh during 1989 90 and it is envisaged to decline further to a level of 7 0 ml/kwh by the end of Eighth Plan period

The consumption of petroleum products in agriculture sector is related to the population of tractors and pumpsets and the extent of their use

Administered prices have been the main instrument to govern the demand for petroleum products Prices of petroleum products have been revised upwards thrice since 1990 These have been done in the background of severe balance of payment crisis to moderate the growth in cor sumption of petroleum products Yet the administered price of kerosene for domestic consumption have not been increased mainly to help the poor who use kerosene for both cooking and lighting On the other hand the price of naphtha and LSHS which are used as feedstock in fertiliser industries are increased in order to reduce the consumption of naphtha and LSHS to promote the use of natural gas as a feedstock The Eighth Plan postulates that flaring of natural gas would be completely eliminated by the end of the plan period During the Plan period the area of administered prices will be reduced so that market prices can directly influence the product wise consumption These aspects have been considered while projecting the demand for different categories of petroleum products in the Eighth Plan

Textiles

The demand for textiles including export demand has been projected at 22 8 million metres in 1996 97 based on the analysis of consumption behaviour in the recent past The production target has been estimated on the basis of the existing and anticipated additional capacity for yarn production The production of yarn however depends primarily on the availability of fibres The fibres consists of natural fibres like cotton and silk as well as manmade fibres like nylon polyster and acrylic The availability of cotton fibre fluctuates with production of cotton On the other hand the production of manmade fib es apart from being capital intensive is also constrained by the availability of petroleum products which form their principal raw material base The cloth production generally consists of pure cotton blended mixed and pure art silk varieties The requirement of cotton yarn has been estimated using the ratio for conversion of yarn to cloth for pure cotton and blended mixed varieties of cloth production The requirement of cotton fibres has been estimated using the ratio of conversion of fibre to yarn On this basis the requirement of cotton has been estimated at 13 7 million bales The projected cloth production from mill sector and decentralised sector have been placed at 3 5 billion metres and 21 2 billion metres respectively

Fertilisers

In order to achieve the growth in agricultural production postulated in the Eighth Plan, the demand for fertilisers in 1996-97 has been projected at 18.3 million tonnes, based on econometric exercises relating fertiliser consumption with agricultural production. The projected demand for fertilisers consists of 11.5 million tonnes of nitrogenous fertilisers, 5 million tonnes of phosphatic fertilisers and 1.8 million tonnes of potassic fertilisers. On the basis of existing capacity as well as new capacity that is likely to be created during the Plan period, nutrient-wise import requirement has been estimated (Table 5.1).

Finished Steel

There has been a progressive rise in the growth of steel consumption. The average annual growth rate in steel consumption has increased from 4.5 per cent during the Sixth Plan (1980-85) to 5 8 per cent during the Seventh Plan (1985-90). In absolute terms steel consumption increased from 10 66 million tonnes in 1984-85 to 14.8 million tonnes in 1989-90, and further to 15.2 million tonnes in 1991-92. The growth in steel consumption had slowed down very much during the period 1990-92 mainly as a result of curbs on imports which affected the general level of activity in the economy. Steel is consumed mainly in the manufacturing sector, in construction and some minor quantities in defence. The demand for steel has therefore been estimated on the basis of past trend in these user sectors. (Table-5.6)

The on-going process of economic reforms and liberalisation is trying to bring about a restructuring of the growth in the manufacturing and construction sectors. As a result, metal products and metal processing industries are expected to register a higher growth than chemical and metallurgical process industries. These factors will influence the growth in consumption of steel in the medium term.

Non-Ferrous Metals

Aluminium, copper, zinc and lead are the major non-ferrous metals that are most widely used in the metallurgical industries. The projections of demand and domestic production of different non-ferrous metals during the Eighth Plan are based on the information available in the Report of Working Group on Non-Ferrous Metals for the Eighth Plan. While some modifications have been made wherever found necessary.

The country is endowed with large deposits of bauxite, with known reserves of the order of 2650 million tonnes. The aluminium industry has made rapid strides in the last two decades which has made the country not only self sufficient but has also enabled us to export alumina as well as aluminium. The present installed capacity of aluminium in the country is 610 thousand tonnes per annum which is expected to reach a level of 772 thousand tonnes by 1996-97. NALCO is expected to export around 38 thousand tonnes of alumina per year, after meeting its own require-ments. The use of aluminium is expanding rapidly in a number of areas such as furniture and fixtures, packaging applications etc , apart from the traditional areas like conduc-tors, utensils, etc . The demand for aluminium has been estimated taking into account the new areas of applications and also the observed growth in consumption in the recent years.

As regards zinc, the proven reserves as on March,1990 are estimated at 7,343 thousand tonnes It is observed that there is a declining trend in the consumption of zinc partly due to changes in technology in the consuming industries (e.g., down-sizing of automobiles, use of thinwall die-casting etc.) and partly due to the use of cheaper substitutes like aluminium and plastics. Zinc is widely used in galvanizing brass-bronze, manufacture of zinc-based alloys, die-casting and chemicals.

Zinc is being replaced with aluminium alloys, stainless steel and plastics for a variety of applications. With the commissioning of Chanderiya smelter in Rajasthan, it would be possible to export around 100 thousand tonnes of zinc annually. However, small quantity of imports would be needed in the terminal year of the Eighth Plan, 1996-97, to meet domestic demand.

The known reserves of lead in the country as on March,1990 are estimated at 1686 thousand tonnes. The rate of growth in the consumption of lead declined during the period 1990-92 due to slackening of growth in industrial production. However, as industrial production is anticipated to pick up during the Eighth Plan period, the demand for lead has been projected to grow at an annual average rate of 4.5 per cent during the Plan period. With the commissioning of Chanderiya smelter, the installed capacity for production of lead is expected to increase from 89.5 thousand tonnes in 1991-92 to 104 thousand tonnes in 1996-97, which would enable the country to meet its demand in 1996-97 with marginal imports of four thousand tonnes in 1996-97.

The demand for copper is presently growing at about 6 per cent per annum. The cost of production of copper in the country is quite high, as compared to international level, because of the low grade ores and also due to the small scale of operations in comparison to world standards. Hindustan Copper Limited (HCL), is presently the sole agency for copper mining and refining. The installed capacity of HCL is envisaged to rise from 47.50 thousand tonnes in 1991-92 to 62.50 thousand tonnes in 1996-97. However, high protective tariff wall in case of copper has been an important incentive for the domestic producer. As the situation changes with tariff and trade reforms,the imports are likely to increase

Rail Transport

Rail transport services cover passenger and freight traffic. Projections are made by end-use analysis   Major commodities which account for a substantial share of the total volume of freight traffic carried by the railways are considered distinctly (Table 5.7).

The volume of transportation requirements in respect of these commodities has been estimated using the rail transport coefficient which indicates the proportion of commodity moving by the rail mode It has been observed that there is a reasonable degree of stability in the rail transport coefficients over the years, except for the unusual years characterised by fluctuations in commodity supply or transport constraints (Table 5 8) These coefficients for the terminal year of the Plan have been projected taking into account variation in the pattern of locational dispersal of production centres (e.g., location of a new thermal power plant at the coal pithead or in the coastal area). The demand for rail freight traffic in terms of Tonne Kilometers (TKMS) have been projected on the basis of the estimated lead distance for a particular commodity. (Table 5 7).

The demand for rail freight traffic in respect of steel and raw materials for the steel industry has been estimated on the basis of the envisaged production plans of the integrated steel plants. This covers (i) saleable steel products, i.e., finished and semi-finished steel products as well as pig iron for sale and (ii) raw materials other than coal, viz., iron ore, limestone, dolomite, manganese ore, etc. consumed by the steel plants

The major portion of coal traffic carried by the railway is for thermal plants. The rail transport coefficient of coal has declined from 76.3 per cent in 1983-84 to about 69.1 per cent in 1991-92 due to location of new thermal power stations at coal pitheads and this trend is expected to continue during the Eighth Plan period. Coal for steel plants, coke ovens and for railways' own use is moved by railways, while the

demand for other consumers is partly met by road movement The rail transport coefficient for coal in 1996-97 has been estimated at 61 per cent

Iron ore from Goa mines to Marmugoa port is transported by waterways through barges while in the case of Kudremukh project, ore concentrates are moved through pipelines for pelletisation Iron ore exported through the ports in the eastern region, viz , Vizag, Paradip and Madras, is transported to the ports by rail. The rail transport coefficient for iron ore has been in the range of 40 to 50 per cent during the last ten years Since a change in pattern of movement of iron ore is not envisaged during the Eighth Plan period, the coefficient for 1996-97 has been projected at 45 per cent

The rail transport coefficient for cement has been varying between 47 and 55 per cent during the 1980s After the announcement of complete decontrol of cement prices, the coefficient rose to 60 2 per cent in 1989-90, but subsequently declined to 58 9 per cent in 1990-91 and 57 5 per cent in 1991- 92 The coefficient is expected to decline further during the Eighth Plan period and get stabilised at around 55 per cent due to wider dispersal of cement production centres which would reduce the lead distance to the consuming centres and would induce a shift to other modes of transport that might be preferred to rail

Movement of foodgrains through railways takes place mainly in respect of inter-state bulk movement and transport from ports in the case of imports Rail transport coefficient for foodgrains has been in the range of 14 to 16 per cent during normal years However abnormal periods such as droughts necessitate longer distance movement of foodgrains to the drought-stricken areas The coefficient was 20 2 per cent and 21 4 per cent during the drought years of 1986 87 and 1987-88 respectively Assuming normal production levels for 1996-97 the coefficient has been projected at 15 5 per cent

The rail transport coefficient for fertilisers has shown a declining trend during the last two decades Availability of natural gas through the pipelines has facilitated the shift in location of fertiliser plants nearer to consumption centres The coefficient has been projected to decline from the average level of 63 per cent during 1989-92 to 60 5 per cent in 1996-97

A part of the petroleum products are moved through pipelines from the refineries while some are also moved through road to meet the demand in the areas close to the refineries The rail transport coefficient of petroleum products has been found to be in the range of 42 3 to 44 5 per cent during the Seventh Plan period (1985-90), while it was 43 6 per cent in 1990 91 and 43 2 per cent in 1991 92 The Kandla-Bhatinda product pipeline is expected to be commissioned during the Eighth Plan period, which would have a capacity to move 6 million tonnes upto Karnal and 1 5 million tonnes thereafter upto Bhatinda This would substantially reduce the demand for movement of petroleum products by rail in the northern region In view of this the rail transport coefficient has been projected at 37 per cent for 1996-97

Railways transport many other commodities such as granite stones, lime stone, gypsum, rock phosphate, timber, paper and paperboards steel manufactures, aluminium electrical goods, glassware coir products jute, oilseeds, sugar, salt, dairy products etc and all these have been categorised as "other goods' The volume of rail traffic of many of these commodities has been declining over the years The rail movement of these commodities depends on various factors such as the comparative cost advantage due to the freight structure in different modes of transport, the flexibility and convenience in handling and intermodal transfer and most important, the time factor in transporting the commodities Although this category of freight traffic is quite remunerative for the railways, priority is generally accorded to movement of core commodities The volume of freight traffic of the category of "other goods" was in the

range of 35 to 37 million tonnes during the last three years and this has been assumed **at 35** million tonnes for 1996-97. (Table 5.7.)

Electricity generation

Electricity consumption is generally classified into the following broad categories: (i) industrial consumption; (ii) agricultural consumption (mainly for irrigation pumpsets); (iii) domestic consumption; (iv) railway traction; (v) commercial consumption; (vi) public lighting; (vii) public waterworks and sewage; and (viii) miscellaneous uses. While a part of the demand for electrical energy is met by captive generation, in balancing consumption demand against supply, total consumption of electrical energy is considered. Thus, both utilities and non- utilities generation of electricity is accounted for in this study.

The industrial sector is the largest consumer of electricity although its share in total electricity consumption has been declining over the years. While this decline in the share can partly be attributed to the faster growth in consumption in other sectors such as in agriculture and household sector, the important reasons are the use of more energy- efficient technologies and adoption of energy conservation measures in some industries. Electricity consumption in the industrial sector can be broadly divided into two categories, viz., consumption by major or large industries and consumption by other industries. The demand for electricity by major industries has been projected on the basis of end-use method. The norms of specific electricity consumption per unit of output in physical terms have been estimated for major industries using the information available in various official documents like the General Reviews of the Central Electricity Authority, the Annual Survey of Industries, the Reports of the Bureau of Industrial Costs and Prices, etc. Energy-intensive industries such as aluminium, steel, cement, fertilisers, paper, etc., account for more than half of the total industrial energy consumption Since the specific electricity consumption in the industrial sector depends on various factors such as the installed capacity, i.e., size of the industrial units, capacity utilisation, quality of power supply, choice of feedstoc', processing technology, etc., these aspects have been studied in detail in estimating the norms for the individual industries. Furthermore, the changes in the processing technology and the modernisation programmes envisaged in the specific industries during the Eighth Plan period have been taken into consideration while projecting the norms of electricity consumption for the plan period (Table-5 9)

The consumption of electricity by industries other than major industries includes the consumption by small registered and unregistered industrial units It is difficult to estimate the specific electricity consumption norms for each industry. The share of electricity consumption by "other industries" in the total industrial electricity consumption in the past has been estimated and this share is not expected to change significantly during the Eighth Plan period (Table-5 10). The projected demand for electricity in the industrial sector has been cross-checked through independent regression analysis, wherein electricity consumption in the industrial sector for the period 1979-80 to 1990-91 has been regressed on the value added in mining, quarrying and manufacturing sector at 1980-81 prices of the corresponding periods The estimated equation is given below:

$$\text{Log } Y = 1.2827 + 0.9564 \text{ Log } X, \qquad (R^2 = 0.9897)$$

where "Y" represents electricity consumption in the industrial sector (in billion kwh), including both utilities and non-utilities, and "X" represents the value added in mining, quarrying and manufacturing, (at 1980-81 prices)

Using the estimated coefficient from the above equation along with the projected growth rate in value added in mining, quarrying and manufacturing for the Eighth Plan, the demand for electricity in the industrial sector for 1996-97 works out to 157.77 Bkwh, as against the projected demand of 155 Bkwh given by the end-use

method. The difference of 2.77 Bkwh could be attributed to the changes in process technologies and other factors considered in the end-use method.

Electricity consumption in the agricultural sector is primarily for the operation of irrigation pumpsets and it depends, therefore, on the number of electric pumpsets in operation and the intensity of their use. There is a strong correlation between the number of pumpsets energised and the consumption of electicity in the agricultural sector, as relvealed by the following regression equation:

$$\text{Log } Y = -14.7933 + 1.59168 \text{ Log } X, \quad (R^2 = 0.984)$$

where "Y" represents the consumption of electricity in the agricultural sector and "X" represents the number of pumpsets energised, and the equation has been estimated using the time-series data of the period,1979-80 to 1990-91.

The demand for electricity in the agriucltural sector for 1996-97 has been projected using the estimated coefficient from the above equation along with the targetted number of pumpsets to be energised by 1996-97. The estimated demand works out to 77.48 Bkwh. The demand has, however, been projected at a slightly lower level at 76 Bkwh assuming that there would be some improvement in the level of efficiency in the use of irrigation pumpsets during the plan period.

There has been a rapid growth in the domestic consumption of electricity during the 1980s.This could be attributed to various factors like the growth in population, urbanisation, income and, most importantly, the expansion of electricity supply in the rural areas. The demand for electricity for domestic consumption has been projected on the basis of the following relationship:

$$\text{Log } Dx = -19.83 + 2.52 \text{ Log } Dy, \quad (R^2 = 0.99)$$

where "Dx" represent the consumption of electricity in the household sector (Bkwh) and "Dy" represents private final consumption expenditure (at 1980-81 prices); the equation has been estimated using the time- series data of the period 1975-76 to 1989-90.

Using the estimated coefficient from the above equation along with the projected estimate of private final consumption expenditure for 1996-97, the demand for electricity for domestic consumption has been projected at 65.46 Bkwh. The demand for electricity for railway traction purposes depends on the actual route kilometres electrified and the volume of goods and passenger traffic on such routes. The demand has been projected on the basis of regression analysis. Two alternative specifications have been attempted for this purpose. In the first specification, the estimated equation is :

$$Y = 0.166516 + 0.890864 \text{ X}, \quad (R^2 = 0.9703)$$

where "Y" represents electricity consumption in railway traction (Bkwh) and "X" represents the route kilometres electrified;the equation has been estimated using the time-series data of the period 1980-81 to 1990-91.

Using the estimated coefficient from the above equation along with the envisaged programme of electrification in the railways during the Eighth Plan period, the projected demand for railway traction works out to 6.79 Bkwh. In the above specification, the demand projection depends mainly on the route kilometres electrified and it does not take into account the volume of traffic in such routes. In order to capture the growth in the volume of traffic in electrified routes, an alternative specification has

been attempted wherein the electricity consumption in railway traction has been related to value added in railway transport sector. The estimated equation is:

$$Log\ Y = 1.3925 + 0.7568\ Log\ X \qquad (R^2 = 0.9772)$$

where "Y" represents electricity consumption in railway traction (Bkwh) and "X" represents the value added in railway transport sector (at 1980-81 prices); the equation has been estimated using the time-series data of the period 1975-76 to 1990-91.

Using the estimated coefficient from the above equation along with the projected growth in value added in railway transport sector, the projected demand for electricity works out to 6.56 Bkwh as against that of 6.79 Bkwh estimated on the basis of the earlier specification. The higher figure of 6.79 Bkwh has been adopted under the assumption that intensity of traffic would increase further with the expansion of railway electrification.

The demand for electricity in the remaining categories, viz., commercial uses, public lighting, public waterworks and sewage pumping and miscellaneous categories, has been projected on the basis of past trends.

The total demand for electricity in the terminal year of the Plan, 1996-97, of all the categories discussed above adds upto 335.84 Bkwh. This estimate has been cross-checked with the estimates obtained from the regression:

$$Log\ Y = -6.9599 + 1.560\ X, \qquad (R^2 = 0.991)$$

where "Y" represents total electricity consumption in the economy, utilities and non-utilities taken together, in Bkwh, and "X" represents GDP at factor cost at 1980- 81 prices; the equation has been estimated using the time-series data of the period 1980-81 to 1990-91

The projected demand on the basis of the estimated coefficient of the above equation works out to 339.07 Bkwh, as against 335.84 Bkwh estimated on the projected demand of individual categories of users. The difference between the two estimates could be attributed to structural changes in the subsectors which are reflected in the projected demand of individual categories

The gross requirement of electicity generation has been estimated on the basis of the above projected demand. The addition to generation capacity has been estimated taking into account the losses in transmission and distribution as well as the requirements of auxiliary consumption, of both utilities and non-utilities The Eighth Plan envisages specific schemes to reduce these loss and has incorporated their impact into the projections. Furthermore, the Eighth Plan also envisages a larger scope for non-utilities in additional generation capacity. The detailed demand-supply balance for electricity for 1996-97 is given in Table-5.10.

Correspondence with input output model projections

A comparision of flows estimated through the material balances has been made with those obtained in the input-output model.(Annexures 5.23 to 5.28) To make the material balance classifications conceptually comparable with the input output classification, aggregation of certain sectors had to be carried out in presenting these tables. The two distributions broadly correspond with each other. The marginal variations that are exhibited between the two distribution are due to the composition effect in the input output sectors i.e., while the material balance projection refers to a specific commodity input output projection refers to all the commodities falling in the relevant sector.

In the present structure of input output model, the transportation needs of commodities are considered in terms of transportation inputs for a particular industry, whereas the commodity-wise transport projections given earlier in this chapter are oriented towards the output of commodities For example the transportation needs of finished steel would be considered in the input output model not as a separate item but as a part of all industries which consume steel And steel would be a part of the many commodities that flow as input to a particular sector Thus a comparison between rail transportation projections based on material balance approach with input-output model projections of rail transport flows is not possible

CHAPTER-6

TRADE SUB-MODEL

This chapter describes the methodologies adopted for the projections of exports and imports for the Eighth Plan period, 1992-97. It is stipulated that foreign savings, during the Eighth Plan, in terms of the ratio of current account deficit to GDP would be reduced from 2.38 per cent on an average for the Seventh Plan period (1985-90) to an average of 1.60 per cent during the Eighth Plan. In order to achieve this goal, the Plan postulates that exports in volume terms would grow at 13.6 per cent per annum during the Eighth Plan as compared to 8.1 per cent recorded during the Seventh Plan. At the same time, imports have been projected to increase at a much lower rate of 8.4 per cent during the Eighth Plan as compared to 10.0 per cent in the Seventh Plan (Table 6.1). The ratio of exports to GDP is postulated to rise from 7.6 per cent in 1991-92 to 11.0 per cent in 1996-97. The average ratio of exports to GDP would substantially increase to 9.60 per cent for the Plan period, as compared to 5.21 per cent in the Seventh Plan. The ratio of imports to GDP is expected to increase from 10.7 per cent in 1991-92 to 12.2 per cent in 1996- 97. The average ratio of imports to GDP works out to 11 62 per cent during the Eighth Plan as compared to 8.33 per cent in the Seventh Plan. The elasticity of imports to GDP would decline from 1.7 estimated for the Seventh Plan to 1.5 during the Eighth Plan. The average ratio of trade deficit to GDP is thus expected to decline to 2 02 per cent during 1992-97 as compared to that of 3.13 per cent during 1985-90. The balance of payments (BOP) scenario envisaged for the Eighth Plan depends, therefore, very much on the growth of exports projected in the Plan. The projection of imports and exports in the plan period are made at 1991-92 prices

EXPORTS

Export projections for individual commodities and commodity groups adopted in the Plan are in the nature of feasible targets estimated on the basis of detailed analysis as well as certain general assumptions. The analysis included the following aspects:

(i) the observed growth in exports in real terms in the recent past, 1986-87 to 1991-92,

(ii) the estimated elasticity of exports with respect to GDP,

(iii) the physical limits for exports of certain commodities in the light of material balance studies, in particular, an assessment of the extent of surpluses available for exports after meeting the domestic demand requirements so that inflationary pressures do not build up in the economy;

(iv) prospects of world trade in general and the possibilities for expansion of exports to the countries in the Asian, African and South and Latin American regions, including introduction of new products as well as exploring new markets; and

(v) detailed econometric analysis of commodity exports at the disaggregated level using appropriate demand and supply functions.

The export projections are also based on certain general assumptions. First, it is assumed that the domestic producers would respond favourably to the recent changes in the industrial, trade, fiscal and monetary policies by expanding capacities for export production and also by competing effectively in the international markets. Secondly, it is assumed that infrastructural facilities such as power and transport, especially port and air shipment facilities, would expand adequately to match the growth in demand for such facilities. Thirdly, it is assumed that the domestic rate of

inflation during the Plan period would remain at a reasonably low level so as to maintain the price-competitiveness. Fourthly, it is also assumed that exchange rate adjustments would take place as and when required.

Export projections at the level of individual commodities and commodity groups are based on certain perceptions about the world markets in general and the potential for expanding export, in particular. The export potential in the medium as well as long term has been evaluated keeping in view the natural resource base and the country's comparative advantage in labour- intensive manufacturing and processing activities. Export projections at the disaggregated level in terms of commodities and commodity groups have later been fed into the Input-Output model for verifying their consistency with the domestic demand and production profile and the projections have been adjusted, wherever necessary, in order to ensure consistency with the economy-wide projections obtained from the Input-Output model.

In the light of the above analysis, it is postulated that exports would grow at the rate of 13.6 per cent per annum in volume terms during the Eighth Plan period from Rs.44292 crores in 1991-92 to Rs.83869 crores in 1996-97 (Table 6.2). Total exports over the five years of the Plan, 1992-97, are placed at Rs.330153 crores. Exports of manufactured goods would account for Rs.250800 crores comprising of 76 per cent of the total exports, while exports of agricultural and allied products would amount to Rs.50235 crores, a little over 15 per cent of the total exports. The changes in the structure of exports over the Plan period clearly reflect the strategy for export growth envisaged in the Plan. Exports of manufactured goods in the Eight Plan are expected to grow at the rate of 15.0 per cent per annum as compared to that of 13.6 per cent in overall exports. Exports of manufactured goods would increase from Rs.32384 crores in 1991-92 to Rs.65114 crores in 1996-97, while its share in total exports would rise from 73.1 per cent in 1991-92 to 77.6 per cent in 1996-97,implying an increase of 4.5 percentage points. Within the manufacturing sector, the objective is to achieve accelerated growth in labour intensive manufacturing activities such as textiles and textile products (e g., readymade garments and coir manufactures) and handicrafts (e.g., gems and jewellery). Moreover, it is also perceived that the prospects of growth in world demand in respect of these items would be much better in the near future. Over the five-year period, 1992-97, textiles and textile products would account for 24.3 per cent of the total exports, while handicrafts would amount to 20 1 per cent.

Exports of agricultural and allied products are expected to grow at 9.4 per cent per annum during the Plan period from Rs.7700 crores in 1991-92 to Rs.12064 crores in 1996-97 The share of these exports in total exports would decline from 17.4 per cent in 1991-92 to 14 4 per cent in 1996-97, mainly to make room for the rise in the share of manufactured exports mentioned earlier. However, it is postulated that exports of processed agricultural products such as marine products, meat products as well as other processed food products like processed fruits and juices would increase at a faster rate as compared to traditional agricultural exports such as tea, coffee, spices, tobacco, etc., which have a relatively lower income elasticity of demand as compared to processed food products. It is also expected that there would be exportable surpluses of rice and sugar which would help to accelerate the growth in exports of these items during the Plan period. Furthermore, the projections take into account the possibilities of higher unit value realisation in respect of certain items of exports due to changes in product-mix, improvement in quality and packaging, etc. The changes in the structure of exports both at the group and commodity level indicate that the export projections are consistent with domestic resource cost in respect of many items. The export basket would consist more of labour-intensive (and less capital and energy-intensive) commodities.

IMPORTS

Import projections for the Eighth Plan have been made essentially on the basis of the import coefficient matrix of the Input-Output model. The import coefficient matrix, which was originally constructed using past data on import flows, has

been updated for the base year imports and prices. Certain coefficients in the import coefficient matrix have been projected for the terminal year of the Plan on the basis of information contained in the report of the Working Group on imports as well as other reports and studies. In this context it may be pointed out that with a view to overcome the severe BOP crisis faced by the country in 1991-92 the base year of the Eighth Plan various measures were undertaken to reduce the volume of imports. As a result actual imports in 1991-92 were quite low as compared to the trends in the previous years. Nevertheless it would not be correct to presume that the measures of import compression and the resulting cut in actual imports should have necessarily led to a reduction in the use of imported inputs in different industries because it is quite plausible that some part of import requirements would have been met through depletion of inventories built through imports in the previous years. This is most likely to be the case in respect of many items of canalised imports where the agencies concerned invariably carry certain level of inventories. Hence it was considered appropriate to estimate the normalised level of imports for the year 1991-92 for use as the base for projections over the Eighth Plan period.

Import projections obtained through the Input Output model have been cross checked with other independent studies. Econometric studies have been carried out using time series data to estimate the relationship between imports and the GDP. Overall import elasticity as well as elasticities for specific commodity sectors with respect to growth in GDP have been estimated and these have been used to cross check the import projections. Imports have been estimated separately for intermediate uses, consumption and investment purposes.

Import projections broadly fall into three categories. The first category of imports consists mainly of what are known as bulk items. These cover eight commodity groups viz. crude oil and petroleum products, fertilisers and fertiliser raw materials, steel, non ferrous metals, coking coal, newsprint and contingency imports such as cereals, pulses and edible oils. The second category includes all other items which are under the Open General Licence (OGL) as well as other miscellaneous imports under licenses. The third category relates to imports which are not covered in the trade data of the Directorate General of Commercial Intelligence and Statistics (DGCIS) but which are reflected in the Balance of Payments data compiled by the Reserve Bank of India.

The estimates of bulk imports have been made on the basis of the demand and supply projections for individual items contained in the material balance studies for selected commodities. The methodology adopted in these studies for various items differ from each other and has been discussed in detail in the chapter on Industry Sub Model. Briefly supply projections have been made on the basis of detailed exercises relating to capacity utilisation and creation of fresh capacities through projects under construction and new projects. Demand requirements have been estimated based on their use as intermediate input in the various sectors of the economy and also their demand for final use. In the case of essential consumer items such as cereals, pulses, edible oils, sugar etc. their demand requirements have been estimated and the gaps between production and demand have been taken as import requirements. These imports have been shown as contingency imports amounting to Rs 7000 crores during the Plan period. In respect of some commodities the projected levels of production have been found to be in excess of domestic demand and such excess supply have been considered to be available for exports.

The second category consists of heterogenous items. Imports of some items in this group have been projected on the basis of their relationship with the growth of GDP while for some other items the projections are based on the recommendations of Working Group on imports. Imports of capital goods have been projected on the basis of its relationship with capital formation while the special import needs in sectors like off-shore drilling, telecommunications, space and other technology intensive areas have been separately taken into consideration. Imports amounting to Rs 55125 crores have been shown as "Statistical Adjustments". These include mainly government

imports including defence imports Such imports have been projected on the basis of past trend

The level and structure of imports envisaged in the Eighth Plan are based on certain general assumptions These are as follows

(i) The balance of payments position would continue to be under strain during the Eighth Plan period However imports of essential items would not be affected The import requirements of the industrial sector would also not be affected due to the continuing reforms in the industrial trade and fiscal policies

(ii) Necessary policy measures would be taken up to reduce the growth in consumption of crude petroleum and its products

(iii) Contingency imports would be kept at around Rs 7000 crores at 1991-92 prices as envisaged in the Plan

(iv) Imports of miscellaneous items would continue to be at around the same level as reflected by their share in total imports in the past and

(v) Finally and most importantly greater flow of direct foreign investment envisaged in the Plan would help in financing the imports of machinery and capital goods at a larger scale

As mentioned earlier imports are expected to increase at an annual rate of 8 4 per cent from normalised level of Rs 62345 crores in 1991 92 to Rs 93314 crores in 1996-97 (Table 6 3) Total imports over the Plan period 1992 97 would amount to Rs 399650 crores Bulk imports would account for Rs 135895 crores representing 34 0 per cent of the total imports Within bulk imports crude petroleum and products would account for Rs 74660 crores (18 7 per cent of the total imports) while fertilisers and fertiliser raw materials would amount to Rs 34474 crores (8 6 per cent of the total imports) The remaining items of bulk imports including contingency imports would account for only 6 7 per cent of the total imports Imports of capital goods i e machinery and transport equipment over the Plan period have been projected at Rs 106140 crores representing 26 6 per cent of total imports The imports of precious and semi precious stones (mainly intended for processing and re exports) amounting to Rs 40446 crores account for 10 1 per cent of the total imports The structure of imports delineated in the Eighth Plan indicates that the major share of import requirements is accounted for by the following broad categories (i) energy imports (ii) commodity imports which are highly energy intensive (e g fertilisers) (iii) commodity imports which are technology intensive (e g capital goods such as machinery) and (iv) commodity imports which are meant for further processing and re exports (e g precious and semi precious stones)

CONSUMPTION SUB-MODEL

The consumption expenditure of the population for different goods and services are generated in the consumption sub-model. The estimates of private consumption are worked out separately for rural and urban areas and within each area for poor and non-poor group of the population. The item-wise consumption estimates for these four groups of population are added to arrive at consumption expenditure for the entire population, which is used in the input-output model. This chapter describes the estimation procedure of private consumption expenditure in base and termin final year of the plan.

The private consumption vector for the base year of the Plan (1991-92) at purchasers prices i.e, prices inclusive of indirect taxes net of subsidies, and trade and transport margins has been generated by the consumption sub-model using aggregate private consumption for 1991-92 at current prices. The aggregate private consumption estimate of 1991-92 has been forecasted from the actual estimate of private consumption obtained from the estimates upto the year 1989-90 made by the Central Statistical Organisation in its National Accounts Statistics. The aggregate private consumption for the year 1991-92 is then bifurcated into rural and urban components on the basis of per capita consumption expenditure differential between the two segments of population as obtained from the consumer expenditure survey of National Sample Survey Organisation (NSSO). The per capita consumption expenditure differential between rural and urban areas for 1991-92 has been set on the basis of its past trend. The sectoral private consumption, separately for people below and above the poverty line in rural and urban areas have been derived first, on the basis of a linear expenditure system (LES) for 11 broad groups of commodities and services. Then within each LES group, the consumption expenditure has been estimated for a number of items using consumer demand functions. This way, the private consumption expenditure of different commodities and services are estimated separately for the above four groups of population The sectoral consumption of the above four groups of population are added to obtain the sectoral consumption for the country as a whole These estimates of consumption are expressed in terms of purchasers prices, i.e., it includes indirect taxes net of subsidies and trade and transport margins of the commodity concerned The vector of consumption at market prices is obtained by netting out the trade and transport margins from the consumption expressed at purchasers prices. The trade and transport margin rates are determined exogenously.

The final demand vectors of private consumption have been generated for the base (1991-92) and the terminal year of the Plan (1996-97) as well as for the perspective period The methodology behind generation of private consumption vector is outlined below.

The aggregate private consumption obtained from macro economic projection articulated through the macro model is divided into rural and urban areas using the following relations.

$$C = C_r + C_u \qquad \text{........ .... (1)}$$

$$\bar{x}_r = C_r/12\, P_r \qquad \text{.............................(2)}$$

$$\bar{X}_u = C_u/12\, P_u \qquad \text{............ .... (3)}$$

$$\bar{X}_u = b\, \bar{X}_r \qquad \text{... .... (4)}$$

where,

C = Total private consumption as given in macro model

C_r = Total private consumption in rural areas

C_u = Total private consumption in urban areas

$\overline{X}_r$ = Monthly per capita total private consumption in rural areas

$\overline{X}_u$ = Monthly per capita total private consumption in urban areas

P_r = Population in rural areas

P_u = Population in urban areas

b = Estimate of the ratio of per capita consumption in urban to that in rural areas.

The monthly per capita total consumption (x) is assumed to be distributed lognormally in both rural and urban areas.

The lognormal distribution function is specified as:

$$dF(x|\mu,\lambda) = \frac{1}{\sqrt{2\pi}\lambda x} \; exp[-\frac{1}{2\lambda^2} \; (\log x - \mu)^2]dx \quad ....(5)$$

where μ and λ are mean and standard deviation of log x of the distribution. For this distribution,

$$\mu = \log \overline{x} - 0.5 \; \lambda^2 \quad ....(6)$$

Here $\overline{x}$ is the mean monthly per capita consumption expenditure, which is $\overline{x}_r$ in rural areas and x_u in urban areas.

Using an exogenously determined poverty line (x^*), the percentage of people below the poverty line, considering the distribution function specified in (5) is estimated as:

$$p_b = \varphi (y^*) \cdot 100 \quad ....(7)$$

where,

P_b = Percentage of people below the poverty line.

$$y^* = (\log x^* - \mu)/\lambda \quad ....(8)$$

x^* = Poverty line, and

φ = Normal distribution function with zero mean and unit variance.

The inequality parameter λ of the log normal distribution is estimated from the Lorenz ratio of monthly per capita household consumption expenditure distribution in rural and urban areas obtained from the NSS data, using the relation given in (9) below.

$$LR = 2\,\varphi\,(\,\lambda\ /\sqrt{2}\,) - 1 \quad ....(9)$$

where LR = Lorenz ratio of the consumption expenditure distribution.

From (9), $\lambda = \sqrt{2}^{-} \cdot \varphi^{-1}\,[(1 + LR)/2]$ ....(10)

where φ^{-1} = Ordinate of the standard normal curve,

The aggregate mean per capita consumption in rural and urban areas are decomposed into poor and non-poor group of population within each area using (11) and (12) in the following way.

Average per capita consumption for people below the poverty line, i.e., for poor group of the population is estimated from (11)

$$\bar{x}_p = \bar{x}\ \varphi\,(y^{\bullet} - \lambda\,)/\,\varphi\,(y^{\bullet})\quad ....(11)$$

where $\bar{x}_p$ = per capita consumption of people below the poverty line $(x^{\bullet})$

Average per capita consumption of people above the poverty line, i e , for non-poor group of population is estimated from (12)

$$\bar{x}_{np} = \bar{x}\ [\ 1 - \varphi\,(y^{\bullet} - \lambda\,)\ ]/\ [\ 1 - \varphi\,(y^{\bullet})]\quad ....(12)$$

where $\bar{x}_{np}$ = per capita consumption of people above the poverty line, i.e., for non-poor group of population.

By definition,

$$\bar{x} = \bar{x}_p\,\varphi\,(y^{\bullet}) + \bar{x}_{np}\ [\ 1 - \varphi\,(y^{\bullet})]\quad ....(13)$$

In general, the per capita consumption of a range of population (i,j) is estimated from the lognormal distribution specified in (5) as

$$x_{ij} = \frac{\bar{x}\ [\varphi\,(y_j^{\bullet} - \lambda\,) - \varphi\,(y_i^{\bullet} - \lambda\,)]}{[\varphi\,(y_j^{\bullet}) - \varphi\,(y_i^{\bullet})\,]}\quad ......(14)$$

where,

$$y_i^{\bullet} = (\log y_i - \mu\,)\ /\ \lambda\quad \text{and}$$

$$y_j^{\bullet} = (\log y_j - \mu\,)\ /\ \lambda$$

The sectoral private consumption demand for people below and above the poverty line within each area are estimated separately. The estimation is carried out in two stages. First, the sectoral consumption demand is derived for people

below and above the poverty line, in rural and urban areas on the basis of a Linear Expenditure System (LES) comprising 11 groups of commodities and services. The LES parameteres are estimated separately for poor and non-poor group of population within rural and urban areas.Then in the second stage, a set of consumer demand functions estimated from National Sample Survey data on consumer expenditure are utilised to obtain the consumer demand for different commodities and services each for people below and above the poverty line in rural and urban areas. The independent estimates of sectoral consumption demand obtained from consumer demand functions and LES are found to differ. The difference in the consumption between the two sets of estimates are closed by adjusting the consumption demand obtained from consumer demand functions, pro-rata, to that obtained from the Linear Expenditure System within each LES group. The adjusted sectoral consumption demand for people below and above the poverty line in rural and urban areas are added to obtain the sectoral consumption demand at the aggregate level. This estimate of sectoral consumption demand which is at purchasers prices, are converted into market prices after netting trade and transport margins from it. The sectoral consumption demand at market prices estimated from consumer demand functions and linear expenditure system are mapped into 60 sectors of the input-output model.

Consumer Demand Functions

The consumer demand functions are obtained by estimating Engel curves on application of single equation weighted least squares method, weights being proportion of population in each expenditure class, for commodities or commodity groups for which cross section household consumption expenditure data are available from National Sample Survey for the year 1983. The functional form is determined by relating per capita consumption expenditure of a commodity or commodity group to the aggregate per capita expenditure. In all, six forms of functions are tested to locate the best fit. The six forms are:

(a) Double Log : $\log C_i = a + b \log C$

(b) Semi Log : $C_i = a + b \log C$

(c) Log Log inverse : $\log C_i = a + b \log C + d/C$

(d) Log Inverse : $\log C_i = a + b/C$

(e) Linear : $C_i = a + b C$

(f) Hyperbola : $C_i = a + b/C$

where,

C_i : monthly per capita expenditure of the i-th commodity.

C : monthly per capita expenditure for all commodities.

The best fitting Engel curves among these are chosen separately for each commodity and population group on the basis of their coefficient of determination adjusted for degrees of freedom and the form of function. In case of commodities for which data were too inadequate to estimate a demand function, aggregate consumption proportions have been used so that in such cases the demand is estimated from the relation,

$C_i = bC$.

The Engel curves are estimated separately in rural and urban areas and within each area, separately for people below and above the poverty line

Linear Expenditure System (LES)

Linear expenditure system is a complete demand system which is derived from the additive utility function The utility function may be specified as

$$U(q) = \Sigma \ b_i \log (q_i - c_i) \qquad (15)$$

such that $\quad \Sigma \ b_i = 1$

and $\quad q_i > c_i$

Here q_i represents quantity consumed of the i-th commodity and b_i are marginal budget shares c's are sometimes interpreted as committed quantities This interpretation is only suggestive and fails when any c_i is negative A negative c_i is, however not inconsistent with theory

Maximising (15) subject to budget constraint

$$C = \Sigma \ p_i \ q_i \qquad (16)$$

where p_i is the price of i-th commodity and C is the monthly per capita total expenditure incurred on various commodities or commodity groups

The complete demand system (LES) obtained from above can be specified as

$$C_i = p_i q_i = c_i p_i + b_i (C - \Sigma \ c_i p_i) \qquad (17)$$

$$i = 1 \qquad n$$

The fulfilment of the second order condition of utility maximisation requires

$b_i > 0$ for all i

which means absence of inferior commodities and

$C > \Sigma \ c_i p_i$

where $C_i=$ Monthly per capita expenditure on i-th commodity As the LES can be derived from a utility function, it satisfies all the theoretical properties namely, adding up, homogeneity and symmetry of Slutsky substitution matrix

By incorporating random disturbances in (12) LES can be specified as

$$p_{it} q_{it} = c_i p_{it} + b_i (C_t - \Sigma_k c_k \ p_{kt}) + e_{it} \qquad (18)$$

$$t = 1, \qquad ,n$$

such that

$$E(e) = 0$$

$$E(ee') = \Omega(+)1$$

Since the adding up property implies that $I\Omega = 0$, Ω becomes singular and poses estimation problem. This is overcome by deleting one equation from the system. Without loss of generality we delete the last equation and formulate the likelihood function. Denoting the truncated residuals as $\overline{e}_t$, b and $\overline{\Omega}$ for e_t, b and Ω respectively, the likelihood function in logarithmic form can be written as,

$$LnL = -\frac{1}{2} m(n-1)ln2\pi - m/2ln(det\,\overline{\Omega}) - \frac{1}{2} \Sigma_t(e'_t\,\overline{\Omega}^{-1}\,e_t) \quad ....(19)$$

The first order conditions of the maximum likelihood function entails non-linear equation in parameters and the estimates can be obtained only by applying iterative methods such as Gauss Newton, Newton Raphson methods. The solution vector does not yield the estimate for the last b, i.e. b_n, which is obtained from the relation.

$$\Sigma b_i = 1$$

The performance of the model is judged by computing

$$R_i^2 = 1 - \Sigma e_{it}^2 / \Sigma_t(V_i - \overline{V_i})^2 \quad ... \,...(20)$$

Where, V_t is average expenditure of i-th commodity. It can also be judged by using Thiel's average information inaccuracy given by,

$$\pi = 1/m \;\; \Sigma_i\Sigma_t\,W_{it}\,ln\,(\hat{W}_{it}\,/\,W_{it}) \qquad ....(21)$$

The LES parameters have been estimated from the time series of cross section data generated from the National Sample Survey on consumer expenditure relating to the rounds 24th (1969-70) through 28th (1973-74), 32nd (1977-78) and 38th (1983) using Gauss Newton maximum likelihood procedure. Commodity group price indices with 1969-70 as base have been compiled from the wholesale price indices available from the Office of the Economic Adviser, Ministry of Industry. Separate weights, based on the NSS 32nd round consumer expenditure data, have been used for rural and urban areas.

Adjustment of Parameters of LES and Engel/Demand Functions

The estimated parameters of LES and of Engel/Demand functions are adjusted in such a way that the private consumption vector for 60 sector input-output table of the base year (1991-92) generated by these functions agree with the one independently estimated by commodity flow approach, i.e., that obtained from National Accounts Statistics. The procedure adopted is:

(i) The aggregate private consumption of the base year of the plan (1991-92) is first bifurcated into rural and urban components using (1) to (4) and then each into two parts, for people below and above the poverty line, using (5) to (10). This, inter-alia, assumes that monthly per capita private consumption in 1991-92 follows a lognormal distribution with the mean consumption as derived from the macro

model and the inequality parameter as estimated from the NSS data on consumer expenditure of 43rd round (1987-88)

(ii) Using the monthly per capita total consumption in rural and urban areas and within each area for people below and above the poverty line, obtained from (i) and the adjusted LES and consumer demand functions, the sectoral private consumption is estimated

(iii) The coefficients of demand functions/Engel curves derived from NSS data of an earlier year are used for projection of consumption demand after updating the same to the prices prevailing in the base year (1991-92) of the Eighth Plan, for use in the consumption model The parameter estimates based on the NSS data have been updated for 1991-92 prices using the relations outlined in (a) to (f) below

     (a) Double Log

$$a' = a - b \, (\log PC) + \log PC_i$$

$$b' = b'$$

     (b) Semi Log

$$a' = aPC_i - b \, PC_i \, (\log PC)$$

$$b' = b \, PC_i$$

     (c) Linear and Proportion

$$a' = a \, PC_i$$

$$b' = b \, PC_i/PC$$

     (d) Log Inverse

$$a' = \log PC_i + a$$

$$b' = PC \quad b$$

     (e) Log log Inverse

$$a' = \log PC_i - b \log PC + a$$

$$b' = b$$

$$d' = PC \quad d$$

     (f) Hyperbola

$$a' = a \, PC_i$$

$$b' = b \, PC_iPC$$

a' b' and d' : Parameters at 1991-92 prices

a b and d : Parameters at 1983 prices

PC_i = Price relative of commodity i for 1991-92 vis-a-vis 1983

PC : Overall Consumer Price Index in 1991-92 vis-a-vis 1983

(iv) Using the monthly per capita total consumption obtained as in (i) and the LES demand function, the LES estimate of the total private consumption for eleven groups of commodities are estimated.

(v) The private consumption of various commodities and services belonging to each LES group are estimated by their respective consumer demand functions. These estimates are pro-rata adjusted to the corresponding consumption demands estimated by LES in (iv). The sectoral estimate of private consumption is then grouped into 60 sectors of the input-output model. The sectoral estimates of private consumption are compared with those estimated by the commodity-flow method and are suitably adjusted so that the percentage difference of the two sets of estimates does not generally exceed 10 to 15 per cent. The private consumption vector of 60 sectors obtained in this way, is used for the base year input-output table. It is also used to adjust the parameters of LES and demand functions. For this purpose, private consumption of the 60 sectors of input-output table are first aggregated to 11 LES groups. Using these final estimates of LES groups as row control and the aggregate rural and urban private consumption derived from the macro model as column controls, estimates of rural and urban consumption of the 11 LES groups are adjusted by RAS method. This yields the balanced rural and urban consumption vector of LES groups. A similar iterative procedure is used to balance the consumption for people below and above the poverty line within rural and urban areas, using the balanced consumption of these areas obtained earlier. The balanced sectoral consumption obtained for rural and urban areas and within each area for people below and above the poverty line, are used to adjust the parameters of the Linear Expenditure System in the following way.

(a) The parameter a_i is adjusted to :

$$\overline{a}_i = a_i \overline{C}_i / C_i$$

where C_i = original estimates of consumption by LES and

$\overline{C}_i$ = Adjusted estimate

(b) The parameter b_i is adjusted to

$$\overline{b}_i = (\overline{C}_i - \overline{a}_i) / \Sigma (\overline{C}_i - \overline{a}_i)$$

where $\Sigma C_i = \Sigma \overline{C}_i = C$

$\overline{a}_i$ and $\overline{b}_i$ are the adjusted a_i and b_i respectively

(vi) The parameter estimates of consumer demand functions for rural and urban areas and within each area for people below and above the poverty line have been adjusted in a similar way. The estimates of consumption demand for rural and urban areas obtained by the respective consumer demand functions for different sectors comprising each LES group have been first adjusted by RAS method using the sectoral private consumption as row control totals and rural-urban totals of the particular LES group as column control totals. RAS method has been used to ensure consistency in the aggregate private consumption obtained through LES with that obtained independently from commodity flow approach. A similar approach has been followed to work out sectoral demand estimates within a LES group for people below and above the poverty line separately for rural and urban areas.

Using these adjusted demand for each commodity the corresponding parameters of the Engel curves of the commodity have been adjusted in the following way

Using C_i as the original estimates and $\overline{C_i}$ as the adjusted estimate of demand of the commodity the parameters of consumer demand functions are adjusted in the following way

    (a) Double Log Log Inverse and Log Log Inverse

$a = a + \log(\overline{C_i}/C_i)$

$b = b$

and $d = d$ in case of log log inverse

    (b) Other functions

$a = a\ \overline{C_i}/C_i$

and $b = b(\overline{C_i}/C_i)$

where a, b and d are adjusted parameters

These adjusted demand function parameters in (VI) and LES parameters in (v) are utilised to project the commodity demand for terminal year (1996 97)

The Facets of Consumption

The consumption model besides depicting the consumption behaviour of different sections of the population quantifies the extent of the improvement in level of living as a result of increase in per capita consumption expenditure and reduction in the disparity of consumption expenditure between different income classes of the population. The model sets the pattern of consumption in rural and urban areas and within each area for people below and above the poverty line as well as for different fractiles of the population

The model uses an exogenously determined poverty line (expressed in terms of monthly per capita consumption expenditure of the population) to delineate two groups in population i e the poor and the non-poor. The inequality in the distribution of consumption among different expenditure groups in rural and urban areas used in the model are assessed from the NSS data on consumption expenditure distribution. The poverty line and inequality parameters used in the model are given in Table-7 1. The poverty ratios expressed as percentage of people in poverty to total

population in rural and urban areas as well as for the country as a whole, for base and terminal year of the plan are estimated on the assumption of lognormality in the distribution of per capita consumption. These are given in Table-7.2. The monthly per capita consumption for poor and non-poor group of population in rural and urban areas for base and terminal year of the plan are given in Table-7.3. The changes in consumption expenditure during the plan period suggest a relatively higher growth in per capita terms in rural areas as compared to urban areas. The eighth plan projects a relatively higher growth in per capita consumption by 3.61% per year in rural areas as compared to 2.54% per year in urban areas. This will help in closing, however marginally, the per capita consumption expenditure differential between rural and urban segments of the population. Per capita consumption for the country as a whole is projected to increase by 3.42% per year in the Eighth Plan. The increase in per capita consumption of non-poor group of population during the plan period is marginally higher as compared to the poor group as the incidence of poverty reduces from 21% in the base year to 10% in the terminal year of the plan at the background of relatively higher growth in consumption of those in the second decile.

The trend in the share of consumption for different deciles of the population separately for rural and urban areas are estimated in Table-7.4. It shows that : (a) the consumption shares in the lower deciles have increased while that in upper deciles have reduced, (b) the rising or falling trend in the consumption shares has been much sharper after mid-1970s, and (c) inter-temporal changes in the consumption shares have largely been witnessed in rural areas since, the mid-1970s whereas the urban areas have remained insulated from such changes. These trends in the fractile-wise share of consumption are reflected in the trend of the quantitative index of inequality in consumption distribution estimated in Table-7.5. It shows significant decline in the overall index of inequality in the consumption expenditure distribution in rural areas since the mid-1970s The above decline in inequality in consumption expenditure distribution in rural areas may be associated with public intervention programmes in the area of rural poverty alleviation.

Keeping the above in view, the Eighth Plan proposes to raise the share of consumption for lower deciles of the population in both rural and urban areas. The decile-wise share of consumption in base and terminal year of the plan are given in Table-7.6. It shows increase in the share of consumption for people upto the seventh decile in both rural and urban areas during the plan period. It also shows that the rate of increase in the consumption shares are relatively higher in lower deciles.

The per capita consumption of different deciles of the population in base and terminal year of the plan and its growth during the plan period are given in Table-7.7. The increase in per capita consumption of different groups of population during the plan period shows a faster rise for the people in lower deciles as compared to those in the upper deciles. For example, the per capita consumption expenditure of bottom 30% of the population in rural areas is projected to increase at a rate of 5 38% per year during the plan period as compared to 2 71% per year for the top 30% of the population. Similarly, in urban areas, the per capita consumption of bottom 30% of the population is projected to increase by 4 75% per year as compared to 1 57% per year in case of top 30% of the population. This will reduce the disparity in consumption between the poorer segment of the population and the rest.

The structure of consumption for different groups of population in rural and urban areas of the country in base and terminal year of the plan are presented in Table-7.8 and Table-7.9 respectively. The changes in the structure of consumption between base and terminal year of the plan generally shows a shift from food to non-food items. It also shows a reduction in the share of foodgrain in food consumption, particularly of the poorer group of the population in rural areas.

A comparison of the per capita consumption of poor 30% of the population with the total population in base and terminal year of the plan has been made . It

is because the poor 30% of the population generally lead a life which is not considered desirable from the point of view of adequacy and minimum level of living. The consumption scenario in the plan, particularly of the poor 30% of the population in rural and urban areas, in a way, reflect the effectiveness of the plan strategy to benefit the relatively weaker sections of the society.

The assumption of lognormality in the distribution of per capita consumption in rural and urban areas, coupled with the exogenously determined poverty line shows that 21% of the total population are poor in 1991-92. The same assumption in the background of a little reduction in the inequality in expenditure distribution between base and terminal year of the plan coupled with the projected growth in average per capita consumption in the plan shows that the poverty ratio defined as a percentage of poor in total population will be 10% in 1996-97. However, the estimate of poverty ratio in 1996-97 and the consequent reduction in the incidence of poverty between the base and terminal year of the plan is based on two critical assumptions. These are: (a) the assumption of lognormality in the distribution of per capita consumption in rural and urban areas continue to remain valid until 1996-97 and (b) the extent of reduction in inequality in consumption expenditure distribution of the population between 1991-92 and 1996-97. The assumption of lognormality in monthly per capita consumption has been tested from the NSS consumption expenditure data of 43rd round which relates to the year 1987- 88. Since then, it has not been possible to trace the nature of movement of per capita consumption expenditure and its consequent impact on consumption inequality. The increase in per capita consumption between 1987-88 and 1991-92, i.e., between 1987-88 and the base year of the plan and also the increase between the base and terminal year of the plan, i.e., between 1991-92 and 1996-97 may or may not be associated with distributional changes. It is rational to presume that high rate of growth of consumption would improve the distribution of consumption by reducing the disparity in per capita consumption between the poor and the non-poor. Besides, the Government intervention programmes in poverty alleviation which are specifically designed to increase the incomes of the poor through generation of productive assets are likely to act positively towards improvement of the consumption distribution pattern. It is because these incomes are supposed to accrue specifically to the poor group of the population and thereby will have a major impact on the improvement of income distribution. The extent of actual shift that takes place in the distribution as a result of increase in per capita consumption and of public redistributive programmes can only be known with the availability of NSS consumption expenditure data of a later year.

The changes in the distribution of income as a result of both growth and redistributive process may or may not allow the distribution of per capita consumption to remain a lognormal one. The heart of the matter is that the consumption growth in conjunction with income redistributive programmes such as, the Integrated Rural Development Programme (IRDP) and wage employment programmes, such as Jawahar Rojgar Yojana (JRY), etc. may change the pattern of distribution of consumption. It is not certain that the resultant distribution will remain lognormal. This prevents determination of the extent of inequality in the distribution of consumption in terminal year of the plan with enough precision. However, a general reduction in inequality in consumption expenditure is more likely to be the consequence of growth in per capita consumption due to general growth process and growth in per capita consumption of the poor as a result of the redistributive process. It is equally true that quantification of the extent of reduction in inequality and the pattern of distribution of consumption concommittant with reduction in inequality is extremely difficult, if not impossible. The problem is confronted here by assuming a ten per cent reduction in the inequality in distribution of per capita consumption in the terminal year of the plan as compared to the base year. For these reasons, the estimate of poverty in 1996-97 as 10% should be treated with caution. Attempts have been made in the earlier plans to assess the distributional impact of the public intervention programmes for poverty alleviation. But, these efforts have posed more questions than they have answered. It is for this reason no attempt has been made in the Eighth Plan to separate the influence of income growth and distributional changes on the pattern of distribution of consumption of the population

and on the estimate of poverty. An indirect way to test the validity of the assumption of lognormality in the terminal year of the plan may be to compare the poverty ratio estimated from the lognormal distribution function with the poverty ratio estimated from a calibrated distribution of consumption expenditure of the NSSO. For this, NSSO Consumer Expenditure distribution of 1987-88 have been jacked up, pro- rata, by the increase in per capita consumption until 1996- 97. This, inter-alia, assumes identical increase in the per capita consumption of different fractiles of the population. The closeness in the two sets of estimates of poverty, i.e., from the calibrated NSS consumption distribution and lognormal distribution function conform the validity of the assumption of lognormality in the distribution of per capita expenditure in 1996-97. On the other hand, discrepancy in the two sets of estimates may put the assumption of lognormality into test. There are differences in the two estimates as can be seen from Table-7.10 which gives the poverty ratio from the two approaches. Moreover, this discrepancy will widen in case the impact of income redistributive measures arising from public intervention programmes in the area of poverty alleviation are taken into account. It is because the investment in IRDP generates income for the poor group of population. Besides, the rise in income as a result of wage employment programmes will affect the consumption expenditure distribution. Since wage employment pro-grammes generate income for that particular year and not on sustainable basis, the increase in income between 1987-88 and 1991-92 and between 1991-92 and 1996-97 as a result of these programmes will impact on the consumption distribution exactly in the same way as the investment in IRDP.

The increase in consumption of the poor due to public intervention will have a far reaching impact on the consumption distribution pattern. The aggregate impact of public intervention programmes in the area of poverty alleviation is increase in per capita income of the poor. This is certain to change the pattern of expenditure distribution in the terminal year of the plan.

CHAPTER - 8

FUTURE TASK

Indian planning process is at crossroads. The economic reforms initiated in June, 1991 aiming at allowing a greater play for markets replacing the different agents of the Government as dominant decision makers are intended to withdraw the Government from certain key areas of economic decision making and allowing it to refocus its policy intervention. The withdrawal of the Government from detailed licensing and controls of production and investment and trade, warrants a change in the role and the use of formal models in capturing the complex intricacies of the planning process. In the present circumstances, as the role and the shape of planning changes, it is necessary to capture these in a formal quantitative model frame. How and to what extent formal economic models can be used to describe the new scenario is the heart of the question. This requires outlining of:

(a) the existing planning process,

(b) the likely changes in the economic scenario and consequently in the planning process as a result of the reform programmes,

(c) the role of formal quantitative models to capture the existing planning process, and

(d) the extent and the manner and method in which the new scenario can be captured through the use of formal economic modelling.

Existing Planning Process

The existing planning process basically involves:

(a) Spelling out the paradigms of development,

(b) Outlining the strategies for development and the supporting policy environment,

(c) Working out the macro-parameters for growth and its sectoral pattern,

(d) Resource allocation between Centre and States and between sectors,

(e) Detailed allocation of budgetary support, and

(f) Consideration of specific projects, programmes and schemes in the public sector.

The planning process described above covers a wide area and involves various organisations and institutions both within and outside the Government. It involves the Central Ministries, the Reserve Bank of India, the State Governments alongwith grassroot level of administration and the political leadership, besides the Planning Commission. The preparation of Five Year Plan begins with the formulation of an Approach Paper outlining the macro economic dimensions, strategies and objectives of the plan. The Approach Paper is discussed in the Planning Commission and presented to the National Development Council for its consideration and approval. Then it is circulated among the States and the Central Ministries. The State Governments and the Central Ministries, in turn, prepare their respective plans based on the

parameters postulated in the Approach Paper. These plans and programmes are reviewed by the Planning Commission. As a result, a detailed plan is evolved which is presented to the Planning Commission and the National Development Council. The Five Year Plan Document is then prepared, keeping in view the objectives, the plan orientation, development perspective, macro-economic dimension, the policy framework, financing and sectoral profiles.

The Five Year Plans thus framed set out the dimensions of economic growth and development in the country and postulate the macro-economic aggregates, such as resources, savings, investment, income and several broader economic and social requirements. It boils down to laying out an investment profile in terms of economic activities to steer the economy in the desired direction. The Five Year Plan is implemented through Annual Plans which involve allocation of resources between Centre and States and between sectors and more particularly the allocation of budgetary resources. It also involves detailed consideration of projects, programmes and schemes. Sanction of Government expenditure is effected through annual budgets. The allocation of Government resources and expenditure in the annual budgets is made keeping Five Year Plans in view.

The objective of the Central Plan is to strengthen and support the State Plan and also to implement some of the key priorities. The Central plans basically is complimentary to the state plans as it caters the areas where the States are unable to invest due to resource constraint or an area which is not the State's direct concern. The separate plans of the Central and the State Governments constitute the public sector plan. The Planning Commission brings them together through a process of discussions and reviews at various levels and thereby plays a coordinating role between the Centre and the State

The Planning Commission estimates the size of national resources. The balance of payments situation is assessed from a detailed calculation of exports and imports. The incremental capital output ratio (ICOR) is quantified. The sectoral material and social requirements are worked out at sectoral level. The material requirements are related to targeted growth rates and are worked out from the input-output based consistency-cum-investment model. The social requirements are assessed more in a normative manner keeping in view the resource constraint. The overall growth rate is set matching the demand and supply of resources. The sectoral targets of growth are made consistent with the overall rate of growth

The plan sets out a projection of investment for both public and private sector. The public sector planning involves charting out the details of output and investment while the targets for private sector mostly are indicative in nature. The public sector investment caters mostly the infrastructure sectors, such as energy, communication, transport and social sectors such as education, health, basic needs etc. In case of private sector, the Government frames policies and packages of incentives and controls in order to realise the growth rates. An example is foodgrains which are produced in private sector by millions of farmers. The plan target for foodgrain production is achieved by building up of irrigation infrastructure, supply of fertiliser, support prices, and research and extension facilities which is exclusively in public sector.

However, all these factors are not entirely captured by the quantitative framework of the model that is presently in use in the Planning Commission as some of them involve a multi-stage decision making process. The use of formal model is only a part of the planning methodology and the quantitative framework of the plan captures only a part of the entire planning process.

The New Economic Scenario

The economic reforms pursued by the Government since June, 1991 basically consist of:

(a) Short-term stabilisation policies in order to correct the balance of payments disequilibrium through adjustment in the exchange rate, ensuring macro-economic balances through curtailment of Government expenditure, monetary liquidity and market liberalisation through elimination of subsidies and price controls; and

(b) long-term economic reforms under structural adjustment pro-grammes covering deregulation of industry, liberalisation of trade, elimination of protective tariff barriers, privatisation of financial institutions and public enterprises, streamlining of the State sector, privatisation of social programmes and rationalisation of the tax structure.

A series of reforms were undertaken in the above direction since June, 1991. The exchange rate of rupee was adjusted downwards.   Foreign trade regime was liberalised. Tariffs were lowered. Policies in respect of trans-border capital flows were liberalised. Industrial licensing was largely dispensed with. Some of the earlier forbidden areas were opened to private enterprise and steps were initiated towards financial sector reforms. The Government particularly concentrated on fiscal reforms.

The reform process thus aims at dismantling of controls and regulatory measures and seeks to redefine the role of Government and, hence, planning. In the new scenario, the role of planning has to be redefined. The planning process will have to undergo a change in the essential sense that the main responsibility of the Government in the context of development may be restricted to infrastructure and social investment and in those activities where private initiative may not be forthcoming. The Government will have to continue to implement programmes for the poor and the weaker sections. Programmes for social welfare, population control, environmental protection, health and education, at least at the primary level, will continue to be the responsibility of the Government for quite sometime to come.

The market system has brought bountiful benefits since the days of Adam Smith. But this system at every turn in history has created large scale disruption, wreaked havoc on the lives of millions of people and been the subject of constant legal and regulatory correction Keeping this in view, the State will have to intervene for expansion of the market and to make it operate more freely, competitively and with accessibility.

The market needs prospective information beyond those accompanying the price. Here indicative planning has the gap filling role. Expanding the scope of the market and making it freely accessible to all will require supportive and congenial legal framework which makes contractual transactions easy and secure. This will include laws relating to transactions in land, real estate, smoother and more secure working of stock exchange and financial intermediaries including removal of obstacles in the free movement of goods and perhaps consumer protection Regulation of monopolies will be one of the important functions of the Government.

The strong point of market is efficiency. It's weak point is that it has only a short-term view. The market prices are more influenced by available supplies and demand in a limited time horizon. As such, the price-mechanism is inadequate to protect environment and ecology which have long-term consequences. This necessi-tates state intervention and planning. Some of the long-term costs can be built into current costs and prices, but that is also possible only through intervention. Thus, in whichever area society has to take a long-term view, state intervention and planning become necessary. Planning here means taking a long-term view, setting goals and

devising strategies to achieve these goals within the accepted paradigms. There is a complementarity between market as an efficiency promoting device and planning as an instrument of establishing behavioural pattern appropriate for achieving the targets set out in the plan.

The reform process will require imaginative Governmental design and management. The Government will have to have a strong interventionist policy in the area of fiscal and monetary management, trade, education, health and in bilateral negotiations to assure market access. It will also have a direct role in the formulation of Science and Technology policy, financial sector regulation, advancement of environmental protection and in the areas that cannot be left entirely to the market place.

So long as there is a Government and an elected Government, it will be there to do things. So, Government interference will be there. At what stage or level this is the question and that is what is required to be decided and settled. The Government will not abandon its role in the economy and planning, it will suitably refocus it to make it more effective. The role of planning will be to devise the best and most productive strategy applying the least but the most effective interventions and not relying only on efficiency and growth.

Models in Indian Plans

A brief outline of the coverage of formal quantitative models in successive five year plans of India may be worthwhile.

The first five year plan (1951-56) did not have any formal planning model. The basic frame was based on the a single sector growth model of Harrod-Domar, which stressed investment for capital accumulation. Production required capital which could be accumulated through investment and to which the growth rate was directly related.

The model though highly aggregative in nature, underlined the problem of raising the per capita income in the economy. However, it concealed structural aspects of the problem of a steady rate of growth which prevented its use as a tool in detailed quantitative policy making.

The development strategy during the second plan (1956-61) was articulated through Mahalanobis model on the premise that development could be achieved by establishment of a modern industrial sector supported by capital investments and infrastructure building. It was a model of economic growth generated by capital accumulation based on domestic savings and foreign capital. The aggregate investment multiplied by aggregate marginal capital-output ratio produced increases in aggregate output from which an even greater proportion was saved and invested for re-generation of the growth process. The aggregate and sectoral investment allocation was formally related through a four sector model in the Second Plan.

The Third Plan (1961-66) and Fourth plan (1969-74) were based on static multi-sectoral input-output system ensuring terminal year consistency.

The Fifth Plan (1974-79) model was a Leontief static open model ensuring terminal year consistency among sectoral output. It consisted of a macro economic model, an input-output model and a consumption model. The macro economic model provided the projection for income which is consistent with total investment. The input-output model consisted of an inter-industry model where each sector is viewed as producers of outputs and user of inputs from other sectors. The consumption model was used to generate demand for consumption expenditure considering the minimum requirement of poor group of population. The Fifth Plan endogenised private consumption and import and worked out a detailed methodology for mobilisation of

financial resources and financing of the plan. It also explicitly brought poverty alleviation in the plan model. In the Sixth Plan (1980-85), an investment planning model was integrated with the input-output approach.

The model system presently used in the Planning Commission integrated the various features developed since the Fifth Plan and made investment consistent with a long term perspective plan. The existing quantitative model described above thus requires to be adapted in the light of the changes in policy.

The Existing Model

The existing plan model is a multi-sectoral static input-output model, where consumption, export and import are treated as final demand and inter-industry transactions are interpreted as intermediate demands. The output level in each industry necessary to satisfy the total demand, i.e., final as well as intermediate, for the commodity, is decided in the plan model. Thus, the principal objective of the multi-sectoral plan model that is in use, is to derive mutually consistent sectoral output targets and corresponding sectoral investment demands.

The plan model sets out the aggregate growth rate of the economy. The aggregate growth rate is determined from an assessment of the macro economic aggregates such as consumption, savings, investment and net inflow from the rest of the world.

The magnitude of the above macro-economic variables are determined by balancing income and expenditure for a number of alternative growth rate in income and the set which is consistent with resource availability and domestic production supply possibilities is adopted.

A set of income and expenditure identities in combination with input-output model determines investment in the terminal year endogenously. The resources available for investment is also calculated as the growth in Gross Domestic Product, savings, consumption and certain other exogenous variables are known.

Sectoral output is determined by final demand in conjunction with the input-output matrix (Leontief inverse). The final demands are determined exogenously. The Leontief inverse is obtained by endogenising import, consumption and investment. Sectoral imports are derived on the basis of input demand for import, adjusted for import substitution and the assumed import content of consumption and investment. Aggregate demand consists of consumption (public and private), investment (public and private), exports and intermediate goods. The output levels necessary to satisfy these demands are calculated with the help of a 60-sector input-output model. This ensures inter-sectoral consistency in output. The feasibility of the output structure requires a matching with their supply. A family of sub-models are used to estimate the supply potentials of different sectors. The sub-models estimate the supply potentialities of different sectors vis-a-vis investment made in earlier plans, rate of completion of existing projects and capacity utilisation. In effect, the sub-models are used to assess the impact of those variables which are not adequately captured in the input-output frame.

The sectoral disaggregation of final demand of each variable is effected mainly from the sub-models. Sectoral private consumption is obtained from consumption sub-model which estimates the demand for different goods and services at the background of growth pattern of the economy postulated in the plan, a projected growth in population and its rural-urban composition and the existing inequality in the consumption distribution. Subsequently, the consumption patterns are adjusted in the light of likely changes in consumption distribution resulting from specified redistributive policies proposed in the Plan.

In the consumption model, the private consumption is divided into four segments - rural and urban separately for below and above the poverty line. A very detailed modelling is done for assessment of the poverty cut-off point and the pattern of distribution of consumption below and above the poverty line. The consumption basket estimated in the consumption sub-model is dovetailed with the main model to ensure supply-demand balances

The estimates of exports are based on a simulation model whose parameters are basically obtained from econometric estimation procedure. An almost similar method is followed in case of imports although sectoral import requirements are partly estimated in the input-output model aided by help of an import coefficient matrix

The model estimates the investment needs for a desired level of output Sectoral allocation of investment is determined by postulating investment function ICORs are estimated for each sector on the basis of past data. These ICORs are used to determine the secotral investment necessary to generate a desired level of output Investment by destination are converted into investment by source, i e , by production activities with the help of capital coefficient matrix. The potential effect of alternate allocation of investment by destination on sectoral growth rate is measured. Then, these are dovetailed into the input-output model to check their consistency. The model treats public and private investments separately as allocation of investment in public sector is a target while that in private sector is an indicative forecast

Finally the model checks the consistency of output requirements with long term objectives and match the growth potentials of the Plan. The Plan model provides a mutually consistent sectoral output and corresponding sectoral investment This way, the model is capable of ensuring inter-industry consistency. However, social optimality is not ensured under the above frame of multi-sectoral consistency

Economic Modelling in New Scenario

The existing model frame would require necessary changes in view of the changed economic environment in which (a) market will predominate (b) private sector will expand (c) public sector will be more autonomous and be subjected to market forces as the private sector (d) trade with the rest of the world will expand in an environment in which global economic trends and compulsions will have larger impact on the domestic economy and (e) the role of the Government will be confined in the creation suitable environment for growth and development rather than directly taking part in production and trade

Within market economies economic planning has two main functions These are

(a) it must look into the future and announce its likely feature (b) it must define strategies evaluate public projects and control their realisation. It is because neither the Government nor the private sector feel that markets convey all the information required for sound decision with long or medium term implication

The estimates of resources and investment in the Plan is made at constant prices on the tacit assumption that income expenditure equilibrium at constant prices would automatically ensure similar equilibrium at current prices because of identical price elasticity of income and expenditure and similarity in prices of commodities particularly of consumption and capital goods. The actual experience is that price elasticity of expenditure is more than that of income and increase in price of capital goods is faster than that of consumption goods. Thus the realised real investment tends to be lower than the targetted plan investments. The existing model thus ignores the real effect of prices whereas such effects may be significant and may distort the consistency as well as the efficiency of allocations

In regard to prices, a detailed analysis of commodity and factor prices, inflation rate, relation between absolute and relative prices and its impact on different sections of the population, factors causing inflation, role of money supply in inflation and impact of changes in administered price policy including dual-price system, is essential particularly for its short-run implications. Capturing these in a quantitative framework would mean a shift away from the existing fix-price model to a flex price mechanism.

In the new policy regime, the trade sector is characterised by decanalisation of imports and exports, liberalisation of import in key areas particularly of raw materials and capital goods, and for export promotion. It would be necessary to develop econometric models to determine the demand for imports and exports for building up the model for balance of payments.

In a liberalised regime for private investment, analysis of private investment behaviour becomes important. Such analysis has to be carried out separately for critical sectors of the economy treating distinctly the private foreign investment. Investment behaviour in the short run will impact upon financial sector savings and balance of payments accounts. In the medium and long-run, investment behaviour will determine the production possibility frontiers. Thus analysis of investment behaviour will be at the core of the modelling effort in future.

An element of forecasting may be introduced in the model so that critical variables are monitored in the short-run. The feasibility of placketing each of the issues mentioned above into a model structure may be studied from the point of view of data availability and stability. Once these issues are embedded in the existing multi-sectoral input-output model and integrated with the perspective plan, forecasting may be made for short term (one or two years), medium term (five years) and for the longer period (ten to fifteen years) by fixing the horizon in terms of key variables such as land, water, energy, food, housing, population and environment.

Planning has crucial role to play in giving expression to what constitutes the socially desirable objective. Planning has played this role in many countries where free market operates. Planning is needed to create social infrastructure for human development, protection of ecology and regeneration of environment and natural resources, protecting the weak and achieving a certain degree of regional balance in growth. Market cannot probably perform these roles on its own. Planning interventions are required for gently guiding the market for achieving some of the societal objectives to which market being guided by short-term considerations is not very sensitive.

A Perspective on Energy Use Efficiency

Energy is an essential input in all the sectors of economy. Input of energy is a function of technology, structure of the industry, type of feedstock and population of machinaries. Better the technology lesser would be the specific consumption of energy. Demand for different sources of energy like electricity, coal and petroleum products for 1996-97 was projected keeping in view the conservation measures, change in the technology, structure of the industries, population of the machineries such as number of vehicles in road transport, number of engines in railways and number of tractors and pumpsets in agriculture. All these variables change the specific consumption of the energy input and have a bearing on demand for energy. Assessing the expected changes in technology, structure, type of feedstocks and population of machineries during the Eighth Plan, change in energy input coefficients for specific industries in 1996-97 with respect to 1991-92 have been worked out.

(1) ELECTRICITY

a) Agriculture

Electricity consumption in agriculture will increase with increase in irrigated areas, replacement of diesel pumpsets by electric pumps, lowering of water table and increase in the number of older type pumpsets. Consumption of electricity in future will depend mainly on projected population of irrigation pumpsets (Annexure-5.1)

b) Aluminium

The newly set up National Aluminium Co. (NALCO) plant has the lowest specific consumption of electricity among all Indian aluminium plants (about 16000 kwh/T). Remaining aluminium plants are also showing gradual decline in specific electricity consumption. With rising share of NALCO output and technological improvements in other plants, there will be overall reduction of specific electricity consumption in future. Several studies including the one conducted by the National Productivity council (NPC) show that Indian aluminium industry has conservation potential of 8-10 per cent in existing plants. For plants other than NALCO, 5 per cent conservation effect is assumed while deriving the aggregate norms (Annexure-5.2).

c) Iron & Steel

Iron and steel industry has witnessed increase in overall electricity consumption with increasing share of production from mini steel plants Also specific electricity consumption in integrated steel plants has not declined in view of increasing output of flat products. The possibility of a reversal of this trend in near future is remote. In mini steel plants specific consumption is high due to their process technology (Electric Arc Furnace) (EAF). The mini steel plants in view of the envisaged use of sponge iron as raw material are expected to arrest the increasing norm to some extent. Some Integrated Steel Plants (ISPs) have already undertaken modernisation programme Studies show that there is conservation potential of 8-10 per cent in ISPs With full capacity utilisation of Vizag plant and improvement\modernisation in other plants the overall norm of consumption for steel industry is envisaged to go down to some extent in future (Annexure-5.3).

d) Cement

The dry process is overall energy efficient, although it is electricity intensive and there is rise in share of production from dry process. However, specific electricity consumption in cement manufacture has witnessed gradual decrease since the late 1980s as a result of technological improvements viz. adoption of vertical roller mills, high efficiency separators, high efficiency fans, variable speed system etc. The study by the National Council of Cement and Building Materials (NCB) indicate that

14—13/PC/ND/95

there is still scope to reduce the electricity consumption in this industry. This has been taken as guideline in assessing future energy conservation potential in working out the norm of specific electricity consumption (Annexure-5.4).

e) Railways

Indian railways have undergone significant changes in the traction front during last three decades. Till early 1950s, steam locomotives dominated 99 per cent of freight traffic and 93 per cent of passenger traffic. However, dieselisation and electrification have replaced the conventional steam locomotives in a big way since the 1960s because of better traffic potential. At present, about 56 per cent of freight traffic is moved by diesel and about 43 per cent by electric traction leaving insignificant traffic being moved by steam locomotives. In case of passenger services, 87 per cent of traffic is handled by diesel/electric traction and the remaining 13 per cent by steam traction.

Diesel and electric locomotives are comparatively more efficient in terms of energy consumption than steam locomotives. They also provide greater hauling capacity, have sharper acceleration and deceleration and are capable of attaining high speeds. They have less servicing needs and, therefore, their availability for traffic is comparatively more leading to optimisation of line capacity. It has been decided to phase out steam locomotives by the year 2000 A.D. Among the electric and diesel, preference will be given for electrification of more tracks to reduce the draft on petroleum products. These envisage a rise in the input coefficient of electricity in the coming years (Annexure 5.5 and 5.6).

f) Electricity Generation

There is continuous rise in transmission and distribution losses over the years although the rate has been arrested to some extent during the Seventh Plan. The transmission and distribution (T&D) losses can be either due to technical reasons such as energy dissipation in the transmission and distributionn lines, transformers and other equipments used in the system or due to administrative reasons which can be attributed to the meter-reading errors, defective meters, unmetered supplies and pilferage of energy. The increased share of electricity consumption in agriculture and domestic sectors also show some relationship with increase in losses. With various system improvement schemes that are already under implementation, the T&D losses are envisaged to reduce (Annexure 5.7 and 5.8).

g) Fertilizer

Total electricity consumption in fertiliser industry is fast decreasing since last few years due to structural changes. Electricity requirement for fertilizer production depends mainly upon the feedstock used. Gas, as a feedstock, is very energy efficient. After the discovery of natural gas at Bombay high, many of the new plants are based on natrual gas. Change in share of capacities based on different feedstocks is given in (Annexure-5.9). With optimum utilisation of proper feedstocks, the rate in fall of specific electricity consumption in coming years is expected to be high (Annnexure-5.10).

h) Cotton

The input coefficient of electricity in cotton textile industry has remained more or less stable during last few years. It would have shown an increasing trend in view of growing share of production from mill sector. But because of adoption of various efficiency measures in the mill sector, the aggregate specific consumption of electricity for cotton textile industry is envisaged to remain at the same level (Annexure-5.11).

i) Paper

Energy consumption in paper industry depends on various factors such as production process, product mix, type of raw material, capacity utilisation, type, size and design of equipment, degree of integration etc. Small units have comparatively low level of energy consumption due to high percentage of waste paper use and the absence of soda recovery unit. In view of the growing demand, setting up of small units was encouraged upto the Sixth Plan. Small units, however, may not sustain the competition in future due to their higher cost of production on account of use of large scale imported machinery that too which is obsolete. It is unlikely that specific consumption norm will further decline with dominance of bigger units in future. Energy consumption in paper mills in India is much higher than those in the advanced countries like North America, Scandinavia, Germany and Japan. However, different studies by the National Productivity Council (NPC), Bureau of Industrial Costs and Prices (BICP) etc. show that there is scope of about 20-25 per cent overall saving in energy in paper industry. Since electricity energy constitute about 19 per cent of total energy, 5 per cent reduction in specific electricity consumption is assumed for the Eighth Plan (Annexure-5.12).

(2) COAL

(a) Electricity Generation

So far there has been consistent increase in the thermal generation. However, with a view to achieve optimal hydro-thermal mix, it has been decided to increase the share of hydel capacity from Eighth Plan onwards. To maximise the use of natural gas and due to other benefits of gas based units, share of gas based electricity generation within thermal generation will have higher growth in the Eighth Plan. Although there has been increase in specific coal consumption in coal based plants, the efficiency at power plants and likely improvement in coal quality to be supplied to plants may bring down the norm Hence input coefficient of coal in overall electricity generation is envisaged to decline (Annexure-5.13).

(b) Iron and Steel

The Working Group on Coal constituted by the Planning Commission for the Eighth Plan has projected lower coke rates for integrated steel plants envisaging improvement in coking coal quality and better blast furnaces and equipment in new/modernised plants. In view of the liberalised policy by way of delicencing and decontrol of prices and increasing demand for steel, share of mini steel plants is expected to rise in future In case of sponge iron, there will be more gas based production. The input coefficient of coal in steel industry, hence, is expected to go down in future (Annexure-5 14).

(c) Cement

Dry process consumes less coal and as all new plants will be based on dry process, the input coefficient of coal in cement industry will decline. The NPC, BICP and other studies show considerable potential for conservation in the cement industry (Annexure-5.15).

(d) Rail Transport

Share of steam locomotives in rolling stock of railways is declining. Hence, the use of coal is decreasing fast and it will be very negligible by the turn of the century. Coal input coefficient for rail transport will further decline in Eighth Plan (Annexure-5.6).

(3) PETROLEUM PRODUCTS
(a) Agriculture

Although diesel pumpsets are being replaced by electric ones, increase in agricultural activitiy has led to increase in number of tractors which is likely to result in an increase in input coefficient of diesel in agricultural sector (Annexure-5.1).

(b) Fertilizer

Increase in share of fertilizer production from gas based plants and consequent decline in share of naphtha and furnace oil based plants in the Eighth Plan is likely to reduce the input coefficient of petroleum products in fertilizer industry (Annexure-5.16).

(c) Iron and Steel

In steel industry, petroleum products are used mainly for (i) flame stabilisation in blast furnace; (ii) calcining and (iii) local transport within the steel plant. The offtake of petroleum products is mainly by the integrated steel plants. Naphtha, high speed diesel and minor quantities of LDO and LSHS/FO are the various petroleum products used in steel industry. Naphtha is used only in Bhilai steel plant. Its consumption which averaged about 25 thousand tonnes in the last few years is likely to remain unchanged during the Eighth Plan. In Visakhapatnam steel plant, the electricity generation (captive) is through steam turbine utilising blast furnace gases. Upgradation of technology facilitating automatic transport of material from blast furnace to steel shop floor would result in reduction in specific consumption of petroleum products. Modified skid system in reheating furnaces would also result in saving of fuel consumption in steel industry (Annexure-5.17).

(d) Electricity Generation

Specific consumption of oil in thermal generation is on the decline due to improvement in technical efficiency of the plants and overall improvement in the Plant Load Factor (PLF). With increasing share of power generation from gas based plants, the use of petroleum products in total power generation would reduce as they are required only in steam plants for flame support at initial start-up. This is likely to result in a decline in the input coefficient of petroleum products in total electricity generation (Annexure-5.18).

(e) Other transport services

This sector includes mainly road transport services whose physical output at macro level is rather difficult to quantify. Value added in this sector does not reflect much change in input coefficient of petroleum products. Hence a reduction in fuel consumption is possible with replacement of old stock of vehicles with those of fuel efficient ones, betterment of roads, better design of engines, rationalisation of long distance traffic between road and rail etc. Since this is a highly dispersed industry, intensive policy support to achieve conservation is called for (Annexure-5.19).

(4) CRUDE OIL
Petroleum Refineries:

Various measures have been adopted by the petroleum refining industry to contain the refinery losses as a result of which refinery losses are showing declining trend. However, in view of setting up of three new grassroot refineries, the declining trend is likely to be arrested to some extent. Presently, the losses are around 6 per cent (Annexure-5.20).

(5) NATRUAL GAS

(a) Fertilizer

Natrual gas, naphtha, fuel oil and coal for process feed, fuel and steam raising are the principal forms of energy consumption in fertilizer industry. Over the years there has been a change in process technology. While the old fertilizer plants were based on feedstocks like coke, lignite and coke oven gases, with the development of catalytic steam reforming technology, preference was given to light hydrocarbons like naphtha and natural gas for production of ammonia. Due to indigenous availability of large quantity of associated natrual gas in the later half of 1970s, the feedstock policy was reviewed. It was decided to separate lower fractions of associated gas which could be used as feedstock for fertilizer plants. Hence, the share of gas based nitrogenous fertilizer production which was about 20 per cent of the total fertilizer production in 1983-84 is envisaged to rise to 55 per cent in 1996-97. This will increase the input coefficient of gas in fertilizer industry (Annexure-5.16).

(b) Electricity

The generation of electricity from gas based plants which was less than one per cent until the eighties increased to around 4 per cent in 1990. Due to abundance of natural gas and eco-friendly nature of gas based thermal power plants, it is envisaged that gas based plants would play significant role in electricity generation in Eighth Plan. As per capacity addition programme envisaged for the Plan, the gas based generation is likely to be around 26 13 billion Kwh representing about 6 per cent of total electricity generation (Annexure-5.21).

(c) Sponge Iron

Earlier, most of the mini steel plants were based on cent per cent scrap based EAF process technology. Since large quantity of scrap are required to be imported, an alternative route of EAF process based on definite ratios of scrap and sponge iron are being set up. The sponge iron can be produced either with natural gas or coal as a feedstock. Since sponge iron produced with natrual gas as a feedstock is relatively less energy intensive, the policy directions are towards setting up of gas based sponge iron plants. It is, therefore, envisaged that input coefficient of natural gas in steel industry will be increasing in future (Annexure-5 22).

ANNEXURE : 1.1
INPUT OUTPUT COEFFICIENTS 1991-92

Assumption :-

(a) - Estimates as given in Eighth Plan document.

(b) - Based on likely population of electric pumpsets.

(c) - Assuming that 20% saving in power consumption per pumpset is possible. This will be achieved in 20% of pumpset population by 1996-97.

(d) -
i. Based on total population of tractors and diesel pumpsets.
ii. Population of diesel pumpsets in 1996-97, 5.5 million Nos.
iii. 895 liters diesel/pump/year.
iv. 1.035 tonnes of diesel = 1 tonne of oil equivalent
v. Population of tractors in 1996-97, 2.014 Million Nos.
   82.5 tonnes diesel/tractor/year.

284

Electricity Input Coefficient in Aluminium Industry

Plant	1983-84	1984-85	1988-89	1991-92	1996-97
1	2	3	4	5	6
I. Output (000'T)					
NALCO	0	0	78.48	192 0	200
Other Aluminium Plants	220	276.49	278.01	320.3	456
Total	220	276.49	356.49	512.3	656
II. Norms of Electricity Consumption with Technological Change					
NALCO			15954	15954	15954
Other Aluminium Plants	20023	19834	18503	18503	17097(a)
All Plants Average	20023	19834	17942	17548	16748
% Change w.r.t. 1991-92	14 10	13 03	2.25	0.00	-4.56
III. Norms of Electricity Consumption with Conservation Measures Superimposed on Technological Change Effect					
NALCO			15954	15954	15156
Other Aluminium Plants	20023	19834	18503	18503	16242
All Plants Average	20023	19834	17942	17548	15910(b)
% Change w r.t. 1991-92	14 10	13 03	2 24	0.00	-9.33

(a) CEA data shows that there has been fall in aggregate norm of electricity
   consumption in aluminium industry For aluminium plant other than NALCO,
   decline in norm between 1983-84 and 1988-89 was 7 59 percent which is
   carried for 1996-97 also

(b) NPC study shows energy conservation potential of 8-10% in Indian aluminium
   plants. For the year 1996-97, 5% reduction in overall norm anticipated.

Annexure-5.3

Electricity Input Coefficient in Steel Industry

	1980-81	1981-82	1982-83	1983-84	1984-85	1985-86	1986-87	1987-88	1988-89	1991-92	1996-97 (Proj)

Specific Consumption of Electricity in ISP	678.00	607.00	621.00	727.00	728.00	698.00	664.00	682.00	664.00	650.00	570.00 (b)
Specific Consumption of Electricity in MSP	750.00	767.00	785.00	803.00	822.00	859.00	898.00	938.00	980.00	980.00	980.00
Average Specific Consumption of Electricity in all plants	692.00	633.00	655.00	745.00	747.00	734.00	714.00	736.00	728.00	735.00	698.00
% Change w.r.t. 1991-92	-5.85	-13.88	-10.88	1.36	1.63	-0.14	-2.86	0.14	-0.95	0.00	-5.03

(a) due to shift in process technology, from open hearth to LD converter, some fall in specific electricity consumption in ISP anticipated for year 1996-97.

(b) Due to various modernisation & conservation programmes taken up by ISP, 5% decline in norm anticipated.

Electricity Input Coefficients in Cement Industry

1	1983-84 Actuals	1991-92 Actuals	1996-97 Proj.
	2	3	4
	Process Shares (%)		
Wet Process	37	20	15
Dry Process	63	80	85
Total	100	100	100
Total Production of Cement (Mill.Tonnes)	26.70	53.00	76.00
	Coefficient of Electricity input Kwh/Tonnes due to combined effect of Technological and conservation measures		
Wet Process	114	·	
Dry Process	155		
Average	140	120	110(a)
%Change w.r t.1991-92	6 70	0.00	-8.33

(a) Target by NCB

N.B. :   1) There is shift in technology from wet to dry process. It is assumed that by the end of 1996-97, there will be 85% dry capacity.

     11) Although there is increase in electricity consumption in dry process. Study by NCB shows that the overall norm for cement industry is going down.

**Railways:- Combined Effect of Conservation Measures and Changes in Modal Mix of
Traffic on Energy Input Coefficients**

% change w.r t 1991-92		97 24	82 28	36 26	44 23	0 00	0 00	-7.32

(a) NPC & BICP study show that there is energy conservation potential in this industry, 5% efficiency has been assumed for the year 1996-97

N B : Electricity input in fertiliser industry has gone down substantially during the Seventh Plan This is mainly due to higher share of production from gas based plants which are energy efficient

S.No.	Item	Units	1983-84	1985-86	1988-89	1991-92	1996-97
0	1	2	3	4	5	6	7

% Change w r t 1991-92	4 12	2 48	0 00	-5 03

Note (a) Big units have higher specific consumption norms Since
number of small units may not increase due to competition
in future, the norm is unlikely to decline

(b) Indian paper industry has energy conservation potential
of 20-25% For short term, 5% conservation anticipated for
electrical energy

Annexure- 5.13
Coal Input Coefficient in Electricity Generation

ITEM	1983-84	1984-85	1989-90	1991-92	1996-97 (Proj)
1	2	3	4	5	6
Total Electricity generation in utilities (Bill. KWh)	140.17	156.9	245.44	286.71	418.2 (a)
Coal based electricity generation in utility (Bill. KWh)	84.44	96.96	165.26	188.53	272 (b)
Share of Coal based generation (%)	60.2	61.8	67.3	65.8	65.0
Total Coal used for electricity generation including middlings (Mill. Tonnes)	58.03	59.4	111.26	136.9	190 (c)
Kg/Kwh of Coal based generation	0.687	0.613	0.673	0.726	0.699
% Change in Coal Norm w.r.t. 1991-92	-5.37	-15.56	-7.30	0.00	-3.72
	Norms of Coal Consumption in total electricity generation with Technological change alone

Total Coal for Iron & Steel	23 84	24 59	23 54	23 77	28 78	28 69	30 43	32 06	44 00
Coal Kg /Steel Kg	2 24	2 04	1 96	1 84	2 06	2 01	2 01	1 90	1 69
% Change in Coal Input w r t 1991-92	17 89	7 37	3 16	-3 16	8 42	5 79	5 79	0 00	-11 05

N B   1   The figures are actuals excepting for 1996-97 which is a projection

        2   Share of production from Mini Steel Plant is likely to increase
            during the Eighth Plan in view of the liberalisation policies

        3   Due to fall in coke rate in ISP's specific consumption of coal in steel industry is going down

296

	1983-84	1991-92	1996-97
1	2	3	4
	Process wise share of capacity		
Wet Proces	37%	20%	15%
Dry Process	63%	80%	85%

N.B. 1. The share of consumption of 4th to 6th, 8th and 9th
decile do not show statisticaly significant trend.
2. The form of function is exponential.
Independent variable is time.
3. Figures in the parenthesis contain t-values.

Sl. No.	Dependent Variable	Constant	Regression Coefficient	$\bar{R}^2$	$\bar{R}^2$
0	1	2	3	4	5
1.	1st Decile	1.0025 (45.47)	0.0128 (17.22)	0.98	0.98
2.	2nd Decile	1.3800 (31.38)	0.0098 (6.65)	0.90	0.88
3.	3rd Decile	1.6800 (47.38)	0.0050 (4.18)	0.78	0.73
4.	4th Decile	1.7600 (36.66)	0.0062 (3.81)	0.74	0.69
5.	5th Decile	1.9200 (34.86)	0.0048 (2.60)	0.57	0.49
6.	6th Decile	2.0600 (30.84)	0.0040 (1.77)	0.39	0.26
7.	7th Decile	2.1600 (51.76)	0.0051 (3.64)	0.73	0.67
8.	10th Decile	3.5400 (24.26)	-0.0110 (2.25)	0.50	0.40
9.	Bottom 30%	2.4900 (78.55)	0.0086 (8.09)	0.93	0.91
10.	Middle 40%	3.3700 (85.06)	0.0050 (3.73)	0.74	0.68
11.	Top 30%	4.0900 (124.96)	-0.0057 (5.16)	0.84	0.81
12.	Bottom 50%	3.2000 (103.86)	0.0070 (6.79)	0.90	0.88
13.	Top 50%	4.3300 (333.51)	-0.0030 (6.85)	0.90	0.88

N.B.:1. The share of consumption of 8th and 9th decile
       do not show statistically significant trend.
     2. The form of function is exponential.
        Independent variable is time.
     3. Figures in the parenthesis contain t-values.

Trend in Decile-wise Consumption Share in Rural Area : 1958-91

Sl. No.	Dependent Variable	Constant	Regression Coefficient	R^2	$\bar{R}^2$
0	1	2	3	4	5
1.	1st Decile	1.2700 (69.15)	0.0042 (4.32)	0.50	0.47
2.	2nd Decile	1.5940 (103.47)	0.0031 (3.82)	0.44	0.41
3.	3rd Decile	1.7770 (137.65)	0.0021 (3.10)	0.34	0.30
4.	9th Decile	2.6870 (312.60)	-0.0012 (2.67)	0.27	0.23
5.	Bottom 30%	2.6670 (189.88)	0.0030 (4.01)	0.46	0.43
6.	Top 30%	3.9430 (460.12)	-0.0009 (1.98)	0.17	0.13
7.	Bottom 50%	3.3800 (351.35)	0.0015 (2.97)	0.32	0.28
8.	Top 50%	4.2570 (1051.14)	-0.0007 (3.05)	0.33	0.29

N.B.:1. The share of consumption in 4th to 8th decile, 10th decile & Middle 40% of the population do not show statisticaly significant trend.
2. The form of function is exponential. Independent variable is time.
3. Figures in the parenthesis contain t-values.

Trend in Decile-wise Consumption Share in Urban Area : 1958-73

Sl. No.	Dependent Variable	Constant	Regression Coefficient	R^2	$\bar{R}^2$
0	1	2	3	4	5
1.	1st Decile	1.1100 (53.61)	0.0107 (4.94)	0.67	0.64
2.	2nd Decile	1.4700 (86.67)	0.0069 (3.89)	0.55	0.52
3.	3rd Decile	1.6700 (118.80)	0.0039 (2.66)	0.37	0.32
4.	5th Decile	1.9500 (199.85)	0.0047 (4.59)	0.64	0.61
5.	10th Decile	3.3900 (113.95)	-0.0113 (3.65)	0.53	0.49
6.	Bottom 30%	2.5500 (178.40)	0.0066 (4.44)	0.62	0.59
7.	Middle 40%	3.4300 (381.44)	0.0025 (2.71)	0.38	0.33
8.	Top 30%	4.0300 (462.25)	-0.0032 (3.50)	0.51	0.46
9.	Bottom 50%	3.2600 (264.54)	0.0053 (4.16)	0.59	0.56
10.	Top 50%	4.3000 (884.35)	-0.0020 (4.01)	0.57	0.54

N.B.:1. The share of consumption of 4th and 6th to 9th
       decile do not show statistically significant trend.
     2. The form of function is exponential.
        Independent variable is time.
     3. Figures in the parenthesis contain t-values.

Trend in Decile-wise Consumption Share in Urban Area : 1977-91

Sl. No.	Dependent Variable	Constant	Regression Coefficient	R^2	$\bar{R}^2$
0	1	2	3	4	5
1.	8th Decile	2.6400 (21.96)	-0.0064 (1.59)	0.34	0.20

N.B.:1. The trend of consumption share in other decile do not trun out to be statistically significant.
    2. The form of function is exponential. Independent variable is time.
    3. Figures in the parenthesis contain t-values.

Annexure 7.8
Trend in Decile-wise Consumption Share in Urban Area : 1958-91

Sl. No.	Dependent Variable	Constant	Regression Coefficient	R^2	$\bar{R}^2$
0	1	2	3	4	5
1.	1st Decile	1.1800 (61.05)	0.0021 (2.07)	0.18	0.14

N.B.:1. The share of consumption in other decile do not show statisticaly significant trend.
    2. The form of function is exponential. Independent variable is time.
    3. Figures in the parenthesis contain t-values.

S.No.	Year	Rural	Urban
0	1	2	3
1	1958-59	0.32588	0.34909

19	1989-90	0.27825	0.35000
20	1990-91	0.27202	0.33054
21	1991-92	0.28726	0.36734

Note:Estimated from NSS Consumer
     Expenditure Distribution.

Annexure 7.10
Trend in Inequality in Consumption Distribution

Sl. No.	Year	Dependent Variable	Constant	Regression Coefficient	R^2	$\overline{R}^2$
0	1	2	3	4	5	6
1. Rural						
a)	1958-73	Log LR	-1.1340 (-72.93)	-0.0083 (5.11)	0.68	0.66
b)	1977-91	Log LR	-0.8300 (-11.05)	-0.0133 (5.25)	0.85	0.82
c)	1958-91	Log LR	-1.1700 (-63.60)	-0.0025 (2.60)	0.26	0.22
2. Urban						
a)	1958-73	Log LR	-1.0150 (-58.49)	-0.0075 (4.15)	0.59	0.55
b)	1977-91	Log LR	-1.2540 (-5.28)	0.0053 (0.67)	0.08	-0.10
c)	1958-91	Log LR	-1.0670 (-59.58)	-0.0006 (0.66)	0.02	-0.03

Legend : LR = Lorenz Ratio of Consumption Expenditure Distribution.

N.B. 1. The form of function is exponential.
      2. Time indicated by year is the explanatory variable.
      3. Figures in the parenthesis contain t-value.
